## Preface

The National Reviews were designed to produce basic data and information for the elaboration of the Pollution Reduction Programme (PRP), the Transboundary Analysis and the revision of the Strategic Action Plan of the International Commission for the Protection of the Danube River (ICPDR). Particular attention was also given to collect data and information for specific purposes concerning the development of the Danube Water Quality Model, the identification and evaluation of hot spots, the analysis of social and economic factors, the preparation of an investment portfolio and the development of financing mechanisms for the implementation of the ICPDR Action Plan.

For the elaboration of the National Reviews, a team of national experts was recruited in each of the participating countries for a period of one to four months covering the following positions:
> Socio-economist with knowledge in population studies,
$>$ Financial expert (preferably from the Ministry of Finance),
> Water Quality Data expert/information specialist,
> Water Engineering expert with knowledge in project development.
Each of the experts had to organize his or her work under the supervision of the respective Country Programme Coordinator and with the guidance of a team of International Consultants. The tasks were laid out in specific Terms of Reference.
At a Regional Workshop in Budapest from 27 to 29 January 1998, the national teams and the group of international consultants discussed in detail the methodological approach and the content of the National Reviews to assure coherence of results. Practical work at the national level started in March/April 1998 and results were submitted between May and October 1998. After revision by the international expert team, the different reports have been finalized and are now presented in the following volumes:

| Volume 1: | Summary Report |
| :--- | :--- |
| Volume 2: | Project Files |
| Volume 3 and 4: | Technical reports containing: |
|  | $-\quad$ Part A: $\quad$ Social and Economic Analysis |
|  | $-\quad$ Part B: |
|  | $-\quad$ Part C: | Wanancing Mechanisms | Water Quality |
| :--- |
|  |
|  |

In the frame of national planning activities of the Pollution Reduction Programme, the results of the National Reviews provided adequate documentation for the conducting of National Planning Workshops and actually constitute a base of information for the national planning and decision making process.

Further, the basic data, as collected and analyzed in the frame of the National Reviews, will be compiled and integrated into the ICPDR Information System, which should be operational by the end of 1999. This will improve the ability to further update and access National Review data which is expected to be collected periodically by the participating countries, thereby constituting a consistently updated planning and decision making tool for the ICPDR.
UNDP/GEF provided technical and financial support to elaborate the National Reviews. Governments of participating Countries in the Danube River Basin have actively participated with professional expertise, compiling and analyzing essential data and information, and by providing financial contributions to reach the achieved results.

The National Review Reports were prepared under the guidance of the UNDP/GEF team of experts and consultants of the Danube Programme Coordination Unit (DPCU) in Vienna, Austria. The conceptual preparation and organization of activities was carried out by Mr. Joachim Bendow, UNDP/GEF Project Manager, and special tasks were assigned to the following staff members:

- Social and Economic Analysis and Financing Mechanisms:
- Water Quality Data:

Reinhard Wanninger, Consultant

- Water Engineering and Project Files:
- Coordination and follow up: Donald Graybill, Consultant, Rolf Niemeyer, Consultant
Andy Garner, UNDP/GEF Environmental Specialist

The Hungarian National Review was prepared under the supervision of the Country Programme Coordinator, Ms. Maria Galambos. The authors of the respective parts of the report are:

- Part A: Social and Economic Analysis: Mr. Judit Rakosi
- Part B: Financing Mechanisms: Ms. Klara Toth
- Part C: Water Quality: Mr. Gyorgy Pinter
- Part D: Water Environmental Engineering: Mr. Sandor Kisgyorgy

The findings, interpretation and conclusions expressed in this publication are entirely those of the authors and should not be attributed in any manner to the UNDP/GEF and its affiliated organizations.

## List of Abbreviations on Water Quality

| kg/a | kilogram per year |
| :---: | :---: |
| kt/a | thousand kilogram per year |
| KÖQ | mean water discharge (arithmetical mean of daily discharges occurring within a given period) |
| KQ | low-water discharge (the lowest discharge within a given period) |
| NQ | high-water discharge (the highest discharge within a given period) |
| $\mathrm{m}^{3 / \mathrm{s}}$ | cubic meters per second |
| $\mathrm{m}^{3} / \mathrm{d}$ | cubic meters per day |
| T/a | tons per year |
| Tm ${ }^{3} / \mathrm{a}$ | thousand cubic meters per year |
| Qualitative abbreviations |  |
| BOD | Biochemical Oxygen Demand |
| $\mathrm{COD}_{\text {cr }}$ | Chemical Oxygen Demand (chromate) |
| $\mathrm{COD}_{\text {p }}$ | Chemical Oxygen Demand (permanganate) |
| MBAS | Methileneblue Anionactive Surfactants (ANA Detergents) |
| N | Nitrogen (generally Total Nitrogen in the Tables of the report) |
| $\mathrm{NH}_{4}{ }^{+}$ | Ammonium ions |
| $\mathrm{NH}_{4}{ }^{-} \mathrm{N}$ | Ammonium nitrogen |
| $\mathrm{NO}_{3}$ | Nitrate ions |
| $\mathrm{NO}_{3}-\mathrm{N}$ | Nitrate nitrogen |
| PAH | Polycyclic Aromatic Hydrocarbons |
| PCB | PolyChlorinated Biphenyls |
| $\mathrm{PO}_{4}{ }^{3-}$ | Orthophosphate ion |
| $\mathrm{PO}_{4}{ }^{\mathbf{3 -}}-\mathrm{P}$ | Orthophosphate phosphorus |
| O\&G | Oil and grease |
| P | Phosphorus (generally Total Phosphorus in the Tables of the report) |
| TDS | Total Dissolved Solids |
| TOC | Total Organic Carbon |
| TPH | Total Petroleum Hydrocarbons |
| TSS | Total Suspended Solids |

## Other abbreviations

| Biol. | Biological |
| :--- | :--- |
| Biol+N-P | Biological treatment with nutrient removal |
| Inhab. | Inhabitants |
| Irr. | Irrigation |
| M Ft | Million Hungarian Forint |
| Mech. | Mechanical |
| Recr. | Recreation |
| Sew\% | Rate of population supplied by public sewer system |
| Sludge tr. | Sludge treatment |
| TPE | Thousand Population Equivalent |
| Ww | Wastewater |
| Wwtp | Wastewater treatment plant |

## 1. Summary

The Part C: Water Quality report consists of two volumes, the Volume I presents the material of the updated National Review of Hungary and the Volume II (Annex 10) contains the basic water quality data of selected monitoring station for further basin-wide studies, covering the period between the years 1994 and 1997.

### 1.1. Updating, Evaluation and Ranking of Hot Spots

The evaluation and ranking of hot spots in the Hungarian part of the Danube basin was carried out on the basis of the general approach and methodology that was debated and mostly accepted by the water quality working group during the January 1998 National Reviews Workshop. The most important wastewater dischargers were evaluated on the basis of detailed analysis and the assessment of priority ranking was made into three priority groups, such as high, medium or low priority. The given high priority ranking indicates that the source of emission has outstanding importance in Hungary, its impact on the recipient river could be transboundary and it is advised to be considered as a significant factor on basin-wide level.

There are five significant towns in Hungary, which were considered as high priority municipal hot spots, and three of them are situated directly along the river Danube:
$>$ BUDAPEST, the capital of the country,
$>$ GYŐR, the center of Győr-Moson-Sopron County, and
$>$ DUNAÚJVÁROS, the center of Fejér County.
Two other high priority municipal hot spots are located directly along the river Tisza:
$>$ SZOLNOK, the center of Jász-Nagykun-Szolnok County, and
$>$ SZEGED, the center of Csongrád County.
Each of these towns was listed as "hot spots" in the Strategic Action Plan as important wastewater dischargers needing urgent pollution control investments.
There are two Hungarian industrial units in the hot spot list of the Strategic Action Plan: the Oil Refinery in Százhalombatta, where the upgrade of the wastewater treatment facilities was considered, and the Tannery in Pécs, where improvement of sludge treatment and waste disposal is needed. The analysis on the industrial polluting sources however resulted in two additional significant industrial units in the sector of chemical industry, which are advised to be considered in the regional pollution reduction studies as new high priority hot spots (the Nitrokémia Rt. in Balatonfüzfő and the BorsodChem Rt. in Kazincbarcika), while the Tannery in Pécs has got lower priority ranking.

Details on wastewater treatment, emission, pollution impact and transboundary implications of the hot spots are summarized in the relevant Tables of the report. Altogether 38 municipal and 27 industrial dischargers were evaluated and ranked into priority groups. Data on agricultural point source wastewater dischargers were available only for 9 units, all of them belonging to the low priority group.

Nation wide database on agricultural non-point source pollution is not available in Hungary at present. Different research studies were carried out during the last decade on small size catchment areas of creeks to assess the magnitude of nutrient loads originated from agricultural land runoff (e.g.: tributaries of Lake Balaton, etc.). Nation-wide agricultural nutrient load assessments were carried out recently by two projects of the Applied Research Programme of the Environmental Programme of the Danube River basin. Main findings of these projects are presented.

### 1.2. Updating, Analysis and Validation of Water Quality Data

The existing hydrological surface water observation network to monitor the quantitative characteristics of the river system in Hungary consists of 2700 stations, of which 370 are considered to be basic stations. Network diagrams of the river system illustrate the location and types of observation stations. Special attention is given on stations at the border section of rivers entering the country. Source and availability of hydrological observation data (stage/flow), river characteristics, etc. are indicated.

Characteristics of the regular water quality monitoring network running under the requirements of the MSZ 12749 Hungarian Standard are discussed in details, concerning sampling sites, frequency, determinants, data management and classification system. Available data on accidental water pollution incidents are presented. Short information is given on the Danube Accident Emergency Warning System and its Hungarian National Center the PIAC-05.
Data quality control and quality assurance is introduced both for the analytical field and water quality data area. Laboratories working in the field of water pollution control are participating in the intercalibration programme working with quarterly distributed control samples. The most important laboratories are participating also the international Qualco Danube intercalibration and quality assurance programme.

The consistency and comparability of the water quality database is good due to the continuous checking and improvement activities. The length of water quality records, which can be considered homogenous is more than 25 years. Orthophosphate and mineral oil are the exceptions among the traditional components. In respect to the new water quality indices, which were included in the routine analysis since 1994, the accuracy of organic micropollutant data remains questionable due to the low frequency of the analysis. There is no simultaneous flow measurement in the time of sampling, only a reading of the nearest water level gauge is made. Discharge data are obtained from the so-called Q-H rating curves (the relationship between water stage and flow). Systematic correction of discharge data, in close cooperation with hydrologists, started in 1994 and is being currently made.
Flood and excess water control is briefly discussed as well as the conditions of the most important wetlands, and the corresponding water quality problems. Summary on important dams, impoundments and reservoirs are given, and known major water transfers are listed. Information on the source of sediment movements and recent studies on bottom sediment quality of rivers are given in the report.

For the purpose of transboundary diagnostic analysis and basin-wide water quality simulation studies 18 preferred water quality monitoring stations are advised, containing the most important regular water quality monitoring stations at the border sections of rivers entering the country. This list includes all the stations, which are selected monitoring stations for the Trans-National Monitoring Network of the Environmental Programme for the Danube River Basin and also those stations which participate in the Bucharest Declaration Monitoring Programme.
Basic water quality data of the period 1994-1997 are provided for further basin-wide studies. Comments on use and understanding of the elements of this database are given. For better understanding the changes of water quality of these stations, statistics of the recent 10 years period are enclosed in Annex 10, which contains the water quality data series of the 1994-1997 period.

## 2. Updating of Hot Spots

During the recent years intensive studies and planning activities were carried out in Hungary in the field of decreasing the water pollution impacts of polluting sources to improve available background information for pollution reduction programs. Investment programs to develop the wastewater treatment of several important polluting sources have been started. These activities were supported and accelerated by the National Environment Protection Program [1.], entered into force by the Hungarian Parliament on September 1997, and also by the National Master Plan for Wastewater Treatment dealing with the development of sewerage and wastewater treatment of municipalities (towns and villages) in Hungary.
The above mentioned pollution reduction efforts were also promoted by international contributions. Under the activities of the Environmental Programme for the Danube River Basin (EPDRB) the National Review [2.] of the country was prepared by the substantial support of the Ministry for Environment and Regional Policy. This National Review was completed by the end of 1993 and gave a detailed overview on the state of the environment, polluting sources, water uses, nature conservation and institutional background in Hungary. Another essential development was the elaboration of the Strategic Action Plan (SAP) for the Danube River Basin [3.] with the cooperation of the Danube countries.
The Strategic Action Plan among others concentrated on the "hot spots" (significant polluting sources) of the Danube countries, which represent a potential, or actual danger on the quality of the environment, especially on the aquatic environment. The selections of these hot spots however have not been carried out on the basis of similar considerations. As a consequence of this fact, there are significant differences in the importance of the hot spots on the list of from point of view of basin-wide significance of emission impacts.

The list of hot spots submitted to the SAP by the Hungarian authorities also need certain supervision and revision due to two main reasons:
> Significant changes occurred during the recent period in the national economy in Hungary resulting changes also in the emissions especially in the industrial and agricultural sector;
> The use of harmonized evaluation methods in the analysis and ranking of hot spots all over the Danube River basin is applied, which was agreed during the January 1998 National Planning Workshop.

The analysis of the existing point sources of polluters (potential hot spots) faced deficiencies in areas where the available database was not sufficient to consider all the necessary factors for evaluation and ranking as hot spots. Assumptions based on practical knowledge and experience were made in such cases to provide full picture on the investigated emissions. The sector where inadequate data was found in most of the cases was the agriculture. Due to the privatization process during the recent years significant changes occurred and the available existing data sources could not follow them.

### 2.1. General Approach and Methodology

The evaluation and ranking of hot spots in the Hungarian part of the Danube basin were carried out on the basis of the general approach and methodology that was debated and mostly accepted by the water quality working group during the January 1998 National Planning Workshop.

For the purpose of the present study, those wastewater discharges are considered first of all as "hot spots", which have the following disadvantageous impacts on the recipient water bodies:
$>$ The emission cause water quality deterioration downstream from the discharge section to such an extent, which endanger the operation of the nearby water users;
$>$ The emission may cause transboundary pollution effect;
$>$ In case of accidental failure in the technological operation major river pollution incident could occur with transboundary impact.

Starting point of the evaluation is the existing hot spot list of the Strategic Action Plan, which consisted of 16 municipal, two industrial wastewater polluting sources and one wetland rehabilitation problem in Hungary [3.], as follows:

Table 2.1. Hungarian hot spots of the Strategic Action Plan

| No. | Site of polluting source | Recipient | Sector | SAP proposal for development of wastewater treatment |
| :---: | :---: | :---: | :---: | :---: |
| 1. | Békéscsaba | Körös | Municipal | Upgrade: sludge treatm. |
| 2. | Budapest | Danube | Municipal | Upgrade: +220 $000 \mathrm{~m}^{3} / \mathrm{d}$ biol. New: $+375000 \mathrm{~m}^{3} / \mathrm{d}$ biol. |
| 3. | Debrecen | Körös | Municipal | Enlarge: $+40000 \mathrm{~m}^{3} / \mathrm{d}$ biol. |
| 4. | Dunaújváros | Danube | Municipal | New: +30 $000 \mathrm{~m}^{3} / \mathrm{d}$ biol. |
| 5. | Eger | Eger Creek | Municipal | Enlarge: $+4000 \mathrm{~m}^{3} / \mathrm{d}+$ sludge tr. |
| 6. | Gyõr | Rába | Municipal | Enlarge: II. phase biol. + sludge tr. |
| 7. | Kaposvár | Kapos | Municipal | Enlarge: $+5000 \mathrm{~m}^{3} / \mathrm{d}$ biol. |
| 8. | Miskolc | Sajó | Municipal | Enlarge: $+75000 \mathrm{~m}^{3} / \mathrm{d}$ bioltr. |
| 9. | Nagykanizsa | Dráva | Municipal | Upgrade: sludge treatment |
| 10. | Nyíregyháza | Tisza | Municipal | Upgrade: intensification |
| 11. | Sopron | Rába | Municipal | Enlarge: $+7500 \mathrm{~m}^{3} / \mathrm{d}+$ sludge tr. |
| 12. | Szeged | Tisza | Municipal | New: $60000 \mathrm{~m}^{3} / \mathrm{d}$ mech. tr. |
| 13. | Székesfehérvár | Séd-Nádor | Municipal | Enlarge: $+7500 \mathrm{~m}^{3} / \mathrm{d}+$ sludge tr. |
| 14. | Százhalombatta | Danube | Industrial | Oil refinery: upgrade |
| 15. | Szolnok | Tisza | Municipal | New: $50000 \mathrm{~m}^{3} / \mathrm{d}$ mech+ $30000 \mathrm{~m}^{3} / \mathrm{d}$ biol.+sludge |
| 16. | Veszprém | Séd | Municipal | Enlarge: $+13000 \mathrm{~m}^{3} / \mathrm{d}$ biol.+sludge |
| 17. | Pécs | Drava | Industrial | Tannery: waste disposal, sludge |
| 18. | Kis Balaton | Balaton | Wetland | Reconstruction |
| 19. | Zalaegerszeg | Zala | Municipal | Enlarge: $+8000 \mathrm{~m}^{3} / \mathrm{d}+$ sludge tr. |

There are three main objectives of the analysis on those hot spots, which represent significant loads through their discharges into the recipient surface water bodies, as follows:
$>$ to improve the descriptions of existing hot spots to facilitate their comparison and technical and economic evaluation;
$>$ to clarify if major changes or discoveries may have occurred which eliminate the justification for some of the hot spots to be on the list;
$>$ to determine if major changes or discoveries may have occurred which justify the addition of new hot spots to the list.

The quality of surface water is regularly monitored in Hungary, according to the requirements of the Hungarian Standard MSZ 12749 [4.]. The District Environmental Protection Inspectorates are responsible for this activity and the operational areas and headquarters of the 12 Inspectorates are illustrated in Figure 2.1. Classification of the quality of the river system are carried out and disseminated annually. The results of these activities are discussed later in chapter 3 of this report. The latest available water quality map of Hungary (Figure 4.5.) of the year 1996 clearly shows those problem areas with considerable water quality deterioration, where the river system gets high pollutant loads from the existing significant municipal or industrial polluting sources [5]. There are 16 of these quality problem areas, illustrated also in Figure 2.1., and there are also five rivers entering into the country from abroad with considerable pollution load. These rivers are Sajó, Kraszna, Szamos, Berettyó and Maros. Important polluting sources are located within these water quality problem areas, especially where there are small size river courses as recipients getting significant amount of pollutants in the wastewater discharge. For example this is the situation in case of the following areas:

| Area No.4.: | Creek Ikva | - | Sopron town; <br> Area No.5.: |
| :--- | :--- | :--- | :--- |
| Séd-Nádor System | - | Sékehérvár and Veszprém <br> towns, NIKE Industrial plant. |  |
| Area No.8: | River Kapos | - | Kaposvár town; |
| Area No.9: | Creek Pécsi Víz | - | Pécs town; |
| Area No.14: | Creek Eger | - | Eger town; |
| Area No.16: | Creek Kösely | - | Debrecen town |

Significant industrial units are operating in most of the above listed towns and the public sewer systems are loaded by more or less pre-treated industrial wastewaters.
Specific measures are applied for accomplishing the improvement of the previous list of hot spots in Hungary. The most important wastewater discharges (hot spots) are studied in three groups. The first group consists of municipal hot spots (including important towns in Hungary, size of which are above 50000 population equivalents). The second group is the industrial hot spots. The third group contains the known agricultural polluting sources. Characteristic data on municipal and industrial emissions presented in this report were harmonized with the EMIS activities and related data inputs.

The evaluation of the most important wastewater dischargers from point of view of their significance, pollution impacts and priority ranking was carried out considering the following main features:

Critical emissions discharged into the recipient water body;
$>$ Seasonal variations in the emission or in the river's water regime;
$>$ Immediate cause of emissions;
$>$ Root causes of water quality problems which create the pollution case;
> Condition of the receiving waters;
> Vulnerability of downstream water uses;
$>$ Transboundary implications.
As a result of the evaluation concerning the above main features of the most important wastewater dischargers, assessment on priority ranking was made into three priority groups, such as high, medium or low priority.

The priority rankings were developed on the basis of detailed analysis, and the given rankings have the following special general meanings for the Danube River Basin Pollution Reduction Programme:
$>$ High priority indicates that the source of emission has outstanding importance in Hungary, its impact on the recipient river could be transboundary and it could be a significant factor on basin-wide level;
> Medium priority indicates that the source of emission is an important wastewater discharger on national level, needs immediate investments to develop its pollution control facilities because of the significant pollution impact on the recipient water body. Most of the cases there are ongoing investments in this respect.
> Low priority means, that the source of emission also needs investments in the field of wastewater treatment in the close future because its national importance, but the necessary investments are scheduled not earlier then 1999/2000.

The important issue implied by the above priority groups is that only the polluting sources having "high priority" are proposed to be considered in the basin-wide studies of the Danube River Basin Pollution Reduction Programme.
Basic information for the analysis of the wastewater dischargers came from different sources of which the most important sources were as follows:
> the Master Plan for Sewerage and Wastewater Treatment of Municipalities in Hungary [6.] prepared under the guidance of the Ministry of KHVM (Ministry for Transport, Communication and Water Management) in 1996;
> National Environmental Program [1.] developed by the Ministry of KTM (Ministry for Environment and Regional Policy) approved by the Hungarian Parliament in 1997;
$>$ the data sheets on wastewater dischargers of the District Environmental Protection Inspectorates provided for the KTM in 1998 [7.];
> data on the characteristics of important emissions into recipient waters, developed by a special Emission Working Group of the Ministry of KTM, as a Hungarian contribution to the EMIS Sub-Group [8.];
$>$ direct information from different district and central Authorities and Institutions dealing with water quality and pollution control affairs;
$>$ related data from the Annual Statistical Yearbook (1997) of the Hungarian Central Statistical Office in Budapest [9.].

The studies carried out on developing the priorities of important polluting sources also took into consideration the methods and results of the EBRD-EPDRP project entitled "Environmental Project Financing and Investment Action Programme for Hungary" [10.].

Figure 2.1. Water quality problem areas in Hungary caused by polluting sources

### 2.2. Municipal Hot Spots

The existing situation of the sewerage, wastewater treatment and impacts on the recipient waters were evaluated. The evaluation covered all the significant towns in Hungary having wastewater load greater than 50 thousand population equivalents. The analysis ended up with a priority ranking considering the main features of evaluation standpoints discussed above in chapter 2.1.

Municipal polluting sources getting "high priority" ranking are advised to consider them as "hot spots" for the Danube River Basin Pollution Reduction Programme. Summarizing information sheets are provided on these hot spots containing the basic data on which the priority ranking was elaborated.

### 2.2.1. High priority

There are five significant towns in Hungary, which were considered as high priority municipal hot spots from point of view of the Danube Pollution Reduction Programme. Three of these municipalities are situated directly along the river Danube:
$>$ BUDAPEST, the capital of the country,
$>$ GYŐR, the center of Győr-Moson-Sopron County, and
$>$ DUNAÚJVÁROS, the center of Fejér County.
Two other high priority municipal hot spots are located directly along the river Tisza:
$>$ SZOLNOK, the center of Jász-Nagykun-Szolnok County, and
$>$ SZEGED, the center of Csongrád County.
Each of these towns were listed as "hot spots" in the Strategic Action Plan as important wastewater dischargers needing urgent pollution control investments (Table 2.1.)

General information on the main characteristics of the size, the percentage of population supplied with public sewer system (column 5), the quantity of wastewater discharged and also the applied wastewater treatment technology in these settlements are summarized in Table 2.2.

Budapest is outstandingly the biggest point-source wastewater discharge into Danube along the whole Hungarian stretch of the river. Nearly 20 percentage of the population of the country lives here and it is also one of the important industrial centers of the country. The combined sewer system of the Capital gets significant industrial wastewater load with more or less efficient pretreatment. The sewer system has several direct outlets into the river without the necessary treatment. The existing two biological wastewater treatment plants can manage only about 16 percentage of the total dry weather wastewater flow, the remainder is pumped into the river practically without treatment (using only screens and sand traps). The main pollution impact of the Capital on the quality of the river is the high microbiological pollution. Due to the big dilution effect of the river generally no notable change of the most important quality chemical parameters can be observed at the next regular downstream sampling site at Dunaföldvár (rkm 1560.6).

Győr is the most important town in the North-Transdanubian part of the country along the common Hungarian-Slovakian stretch of the river Danube. The town has large industrial sites of national importance. The municipal wastewater treatment plant is under reconstruction and enlargement, the emission discharged from the plant into the recipient river however represents a significant pollution impact from point of view of microbiological quality parameters.
Dunaújváros is a significant town and industrial center of the Middle-Danube area. The sewer system of the municipality provides a nearly full supply for the population but the treatment of the collected wastewater gets only a very poor mechanical treatment. The river flow in this section provides a high dilution effect on the emission discharged into Danube, thus only the microbiological pollution impact is considerable in this respect.

Szolnok is located in the middle of the Hungarian catchment area of the river Tisza. It is an important municipal and industrial center of this area. The existing sewer system of the town serves nearly all of the population, practically there is no wastewater treatment. The wastewater is pumped into the river only after the applied raw mechanical screening. In spite of the considerable dilution effect of the river, there is a one-class quality deterioration downstream from the effluent.

Szeged is the biggest Hungarian town in the lower part of Tisza catchment in Hungary, located near to the south national border. As the center of Csongrád County and the third biggest city in the country (except the Capital), it is a significant administrative and economic power in this region, with considerable industrial production. There is no wastewater treatment plant to treat the sewage collected by the public sewer system. Though there is a considerable dilution effect of the river on the quantity of the direct emission discharge, this is the only effective transboundary pollution impact on the rivers leaving the territory of Hungary.

Table 2.2. High priority municipal hot spots in Hungary

| No. | Municipality | Area <br> Code <br> No. | Population |  | Main recipient | Ww <br> Discharge m3/d | Ww. treatment Technology, Capacity:m3/d |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | 1000 inhab. | Sew. \% |  |  |  |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| 1 | Gyõr | 1 | 127 | 88 | Danube | 37300 | Biol: 80000 |
| 2 | Budapest: North | 2 | 1886 | 90 | Danube | 60000 | Biol: 82000 |
|  | South |  |  |  |  | 70000 | Biol: 72000 |
|  | Untreated |  |  |  |  | 700000 | None |
| 3 | Dunaújváros | 4 | 57 | 96 | Danube | 6200 | Mech: 12700 |
| 4 | Szolnok | 10 | 78 | 96 | Tisza | 13700 | None |
| 5 | Szeged | 11 | 166 | 67 | Tisza | 34700 | None |

The wastewater loads (emissions) of the above five high priority municipal hot spots are summarized in Table 2.3. This table contains the estimated population equivalent values of the raw wastewater and the total load discharged into the recipient waters, concerning the quality parameters of BOD, COD, total N and total P. Data contained in this table are mostly the same, which were provided for Emission Sub-Group by the Ministry of KTM [8.], while the data with (*) sign were provided by the local Environmental Protection Inspectorate, and data with (**) sign are estimations because the lack of available data.

Table 2.3. Wastewater load of the high priority municipal hot spots

| No | Municipality | Main <br> Recipient | Raw water <br> Load in TPE (thousand) | Wastewater Discharge (Tm3/a) | Total load discharged into Recipient waters (T/a) |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | BOD | COD | N | P |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| 1 | Gyõr | Danube | 212 | 16597 | 2300 | 4600 | 423 | 63 |
| 2 | Budapest: North <br> South <br> Untreated | Danube | 286 | 20867 |  | 1020 | 524 | 103 |

| 5 | Szeged | Tisza | **186 | **14500 | **2200 | **5130 | **540 | **90 |

The main issues and facts considered during the priority ranking analysis are summarized in separate Tables for each of the above five high priority municipal hot spots at the end of this chapter (Tables 2.14/18).

### 2.2.2. Medium Priority

The municipal polluting sources of medium priority have outstanding national importance, because most of them are located near a relatively small recipient watercourse, or stream. This unfavorable situation usually generates local water quality problems, due to the generally small flow of the recipient and the high emission load of the wastewater discharge. The most important sensitive areas where these municipal emissions causes water quality deteriorations are illustrated in Figure 2.1. National efforts are already made to improve this situation and in most of the cases investments are running, or are planned to start for the enlarging or upgrading the wastewater treatment facilities in these towns. The municipal wastewater dischargers being ranked into the medium priority group are listed in Table 2.4. These municipal dischargers are advised to be considered on national level and they are not recommended as single "hot spot" for basin-wide studies. The wastewater load of selected medium priority municipal dischargers is listed in Table 2.5.

Table 2.5. Wastewater load of selected medium priority municipal hot spots

| No. | Municipality | Main <br> Recipient | Raw water <br> Load in TPE <br> (thousand) | Wastewater Discharge (Tm3/d) | Total load discharged into recipient waters (T/a) |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | BOD | COD | N | P |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| 1 | Székesfehérvár | Gaja Creek | 211 | 8564 | 302 | 572 | 257 | 36 |
| 2 | Szombathely | Sorok-Perint | 112 | 9125 | 119 | 319 | 137 | 46 |
| 3 | Zalaegerszeg | River Zala | 112 | 5800 | 20 | 226 | 46 | 6.4 |
| 4 | Nagykanizsa | Cigény Ch. | 107 | 6200 | 33 | 363 | 36 | 12 |
| 5 | Pécs | Pécsi-Víz Cr. | 150 | 17000 | 219 | 766 | 122 | 49 |
| 6 | Nyíregyháza | Canals VIII-IX | 45 | 4311 | 51 | 365 | 221 | 18 |
| 7 | Miskolc | Sajó | 200 | 19528 | 222 | 986 | 388 | 130 |
| 8 | Debrecen | Kösely | 209 | 19581 | 458 | 1672 | 544 | 321 |
| 9 | Békéscsaba | Élőviz Ch. | 53 | 5189 | 144 | 581 | 58 | 36 |

The outputs of the analysis of the municipal hot spots resulted in a clear distinction between the national and international (basin-wide) importance of the Hungarian municipal hot spots, listed in the Strategic Action Plan. As a consequence of the present studies, it is proposed therefore to leave out all the medium priority municipal hot spots from the list of the SAP (Table 2.1.) due to their national importance only. These municipal hot spots to delete are:

| Békéscsaba, | Debrecen, | Eger, | Kaposvár, |
| :--- | :--- | :--- | :--- |
| Miskolc, | Nagykanizsa, | Nyíregyháza, | Sopron, |
| Székesfehérvár, | Veszprém, | Pécs, | Zalaegerszeg. |

### 2.2.3. Low Priority

Municipal wastewater dischargers ranked as low priority hot spots are generally towns with population under 50 thousand, having public sewer system and wastewater treatment plant. The efficiency of the treatment generally needs upgrading and modernization.
The emissions from these plants in most of the cases represent overload of the recipients, except in case of Danube (Vác, Baja, Százhalombatta) and river Sajó (Kazincbarcika). The municipal hot spots with low priority are listed in Table 2.6.

Table 2.6. Low priority municipal hot spots in Hungary

### 2.2.4. Ongoing Investments to Develop Municipal Wastewater Treatment

The Hungarian Parliament accepted and put into force the governmental programme to assist the healthy drinking water supply of the municipalities of the country in 1993. Another, but closely linked national program is the program for the sewerage and wastewater treatment of the Hungarian municipalities (towns and settlements) approved in 1996. There is straight overlapping between these programs in case of municipalities located in the area of sensitive drinking water resources, where the urgent solution of adequate treatment and safe disposal of liquid and solid wastes is outstandingly important. Significant towns located in such areas are for example: Győr, Veszprém, Eger, Miskolc, Kazincbarcika. The most important ongoing investments for the development of municipal wastewater treatment facilities are listed in Table 2.7.

Table 2.7. Investments running to develop municipal wastewater treatment

| No. | Municipality | Area Code No. | Main recipient | Priority | Investment and schedule |

| 12 | Eger | 8 | Eger Creek | Medium | Wwtp enlargement : 1997 / 1999 |
| 13 | Debrecen | 9 | Kösely | Medium | Wwtp enlargement Phase II :1998/1999 |
| 14 | Szolnok | 10 | Tisza | High | New wwtp construction: 1995 / 1998 |
| 15 | Szeged | 11 | Tisza | High | New wwtp construction: 1995 / 1999 |

### 2.3. Industrial Hot Spots

There are two Hungarian industrial units in the hot spot list of the Strategic Action Plan: the Oil Refinery in Százhalombatta, where the upgrade of the wastewater treatment facilities was considered, and a tannery in Pécs, where improvement of the waste disposal solution is necessary.

The analysis on the industrial polluting sources resulted in two other significant industrial units in the sector of chemical industry, which were advised to be considered in the regional pollution reduction studies as new high priority hot spots instead of the tannery.

### 2.3.1. High Priority

The Oil Refinery of MOL Rt. in Százhalombatta is an important factor in the national economy and has a key role in the multiple supply for the different users of their products. This industrial complex has a direct emission discharge into the River Danube. Another important issue concerning this important industrial unit is the safety of pollution free operation of the production technology. In October 1997 a significant accidental water pollution incident was caused by this industrial plant on the river Danube in the form of an oil spill. Due to the effective pollution control measures partly carried out by the emergency unit of the industrial plant itself, there was no transboundary effect of this pollution incident.

There are two big chemical industrial units, which were also considered as high priority hot spots. The complex of the Nitrokémia Rt. (NIKE Rt.) is located in the catchment area of Lake Balaton in Balatonfúzfő. The emission of the industrial plant is transferred however into other catchment area, into the Séd-Nádor Creek system, which is a secondary tributary of Danube. There is an up-to-date biological wastewater treatment plant in operation, but the wastewater containing nondegradable chemical pollutants are stored in a wastewater reservoir and released periodically when the water regime of the recipient provides dilution to meet the requirements of the emission standards and permission of the local authorities. Downstream water users have frequent quality problems and complaints.

Another big chemical complex considered as high priority industrial hot spot is the BorsodChem Rt. situated along the river Sajó in Kazincbarcika, which is a primary tributary of the river Tisza. There is also a biological wastewater treatment plant in operation, however it is overloaded and the dilution rate of the recipient river is not high enough. There are problems to meet the emission standards with that part of the effluent containing outstandingly high salt content.
General information on these high priority industrial hot spots are given in Table 2.8., and some of the important characteristics of their wastewater load on the recipient water bodies are illustrated in Table 2.9.

The main issues and facts considered during the priority ranking analysis are summarized in separate Tables for each of the above five high priority municipal hot spots at the end of this chapter (Tables 2.19/21).

Table 2.8. High priority industrial hot spots in Hungary

| No. | Location \& discharger | Area <br> Code <br> No. | Main <br> recipient | Sector | Wastewater <br> Discharge <br> m3/d | Treatment <br> Technology | Ww <br> fine <br> M Ft |
| :---: | :--- | :---: | :--- | :--- | :---: | :---: | :---: |
| $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ |  | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ |
| 1 | Százhalombatta MOL | 4 | Danube | Oil refinery | 62200 | Biological | 0.26 |
| 2 | Balatonfüzfö: NIKE Rt. | 4 | Séd-Nádor | Chemical ind. | 13700 | Biological | 17,93 |
| 3 | Kbarcika: Borsodchem | 8 | Sajó | Chemical ind. | 13500 | Biological | 0,12 |

Table 2.9. Wastewater load of high priority industrial hot spots

| No. | Location and discharger | Main <br> Recipient | Total load |  | Discharged into (T/a) |  |  | Recipients |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | BOD | COD | N | P | TDS | O\&G | Hg |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| 1 | Százhalombatta: MOL | Danube |  | 2494.2 | 8.0 |  |  | 101.7 |  |
| 2 | Balatonfüzfö: NIKE Rt. | Séd-Nádor | 770.0 | 1180.0 | 835.8 | 12.0 | 17410 | 14.3 |  |
| 3 | Kbarcika: Borsodchem | Sajó | 82.0 | 130.4 | 123.4 |  | 7350 | 3.6 | * |

The above three high priority industrial hot spots have no transboundary pollution impacts during their regular operation. However they are considered as sites of potential risks in case of serious technological failures.

### 2.3.2. Medium Priority

Industrial units getting the medium priority ranking are considered as significant industrial sites on national level. They have direct discharges into main recipients like Danube, Tisza and Sajó Rivers, but these emissions generally do not cause significant quality changes in the recipient water bodies. Considerable water quality deteriorations were observed only in case of the small size recipient Séd-Nádor Creek (secondary tributary of the Danube) due to the emissions of the Nitrogen Works fertilizer factory. General characteristics of the medium priority industrial hot spots are summarized in Table 2.10 below.

Table 2.10. Medium priority industrial hot spots in Hungary

| No. | Location \& discharger | Area <br> Code <br> No. | Main recipient | Sector | Wastewater Discharge m3/d | Treatment Technology | Ww <br> fine <br> MFt |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 2.3.3. Low Priority

The following industrial units of the analysis on point-like wastewater dischargers were evaluated as low priority hot spots having no transboundary impacts on river water quality:

Table 2.12. Wastewater load of low priority industrial hot spots

| No. | Location and discharger | Area <br> Code <br> No. | Main <br> Recipien t | Sector | Total load discharged into recipients |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | T/a |  |  |  | Kg/a |

### 2.4. Agricultural Hot Spots

The area where the studies on wastewater dischargers had to face considerable problems because of inadequate data for the analysis was the agriculture. During the recent years significant changes and transitions occurred in the field of agricultural production units, as a result of privatization. The existing agricultural information systems were unable to follow these rapid changes. As a consequence of these processes no reliable data are available at present (even at the Ministry of Agriculture) on the applied technologies and wastewater management of the new, or changed agricultural units.

The only source regarding the existing agricultural emissions was the data coming from the district Environmental Protection Inspectorates [7.] which were collected and evaluated during their pollution control activities carried out over their operational areas and provided for the Ministry of KTM. The analysis of the available agricultural emission data indicated, that none of these wastewater discharges cause such water quality problems in the recipient waters that would result high priority ranking.

### 2.4.1. Low Priority

According to the available data on point-like agricultural emissions, the units studied generally have no major influence on the quality of recipients. Thus only low priority was given to the following agricultural wastewater dischargers:

Table 2.13. Wastewater load of low priority agricultural hot spots

| No. | Location and Agricultural unit | Area <br> Code <br> No. | Main <br> Recipient | Waste water Discharge (m3/d) | Total load discharged into recipient waters (T/a) |  |  |

Figure 2.2. Location of high and medium priority hot spots

### 2.5. Summary Information on High Priority Hot Spots

The following Tables summarize the basic information used for the ranking of high priority municipal and industrial hot spots recommended for the basin-wide pollution reduction studies (Tables 2.14/21). The location of the high and medium ranked hot spots are illustrated in Figure 2.2, where the numberings refers to the items in the corresponding Tables for the purpose of identification.

Table 2.14. Summary of information for the Györ municipal hot spot

| Hot Spot Name | Györ municipal wastewater treatment plant |
| :---: | :---: |
| Critical Emissions | High emission load is presented by the effluent ( $37300 \mathrm{~m} 3 / \mathrm{d}$ ) of the wastewater treatment plant: <br> Because of the emissions exceeding the limit values of the existing regulations 12.2 million HuFt wastewater fine was imposed for the company operating the plant. |
| Seasonal Variations | The quality of the wastewater is equalized during the dry weather flow, changes are observed only in relation of the variations of hydrometeorological conditions. |
| Immediate Causes of Emissions | The wastewater treatment plant has biological treatment technology using activated aeration system after the mechanical stage, disinfection, sludge centrifuges and drying beds. The plant is running with poor treatment efficiency of about 50 percent. |
| Root Causes of Water Quality Problems | There are significant quantity of industrial wastewater discharged into the public sewer system of the town (about $40 \%$ ) with more or less acceptable pre-treatment. Partly this is the cause of the poor treatment efficiency of the plant. Moreover the flow conditions of the small size recipient are also unfavorable, the rate of dilution is low. |
| Receiving Waters | Substantial water quality deterioration is the impact of the emission on the recipient water body: downstream from the effluent the components of oxygen household deteriorate from class III to Class IV, the bacteriological quality fall into the worst V quality class (see Annex 1). |
| Nearby Downstream Uses | There is no sensitive water use downstream from the effluent discharge into the recipient Moson-Danube, however the outer protection zone of the Szögy drinking Highwater resource is affected by the discharge. |
| Transboundary Implications | No transboundary pollution effect on the main recipient. <br> River Danube because of the very long distance from the downstream border section and the significant self-purification capacity of the river. |
| Rank | High Priority |

Table 2.15. Summary of information for the Budapest municipal hot spot

| Hot Spot Name | Budapest public sewer system |
| :---: | :---: |
| Critical Emissions | The Capital is outstandingly the biggest direct polluter of Danube. Most of the wastewater ( $84 \%$ ) collected by the sewer system is pumped directly into the main stream of the river, only after removing the floating rough material by screens. Quality characteristics of this raw wastewater are: $\begin{aligned} & 500-700 \mathrm{mg} / \mathrm{l} \mathrm{COD}_{\mathrm{cr}} \\ & 250-300 \mathrm{Mg} / \mathrm{BOD} \end{aligned}$ <br> The ratio of industrial wastewater discharged into the public sewer is about $40 \%$. |
| Seasonal Variations | Intensive precipitation often causes additional river pollution effect, when the storm-water overflows of the sewer system along the embankment are in operation, and discharge the highly polluted first surface runoff directly into the river. |
| Immediate Causes of Emissions | The main cause of the large emission into the river is the lack of adequate wastewater treatment capacity. The existing two biological treatment plants can handle only $16 \%$ of the total dry weather wastewater flow. In case of low flow conditions in the river there are still high dilution effects on the effluent. |
| Root Causes of Water Quality Problems | Though the sensitive water intakes are much farther downstream from the Capital's discharge, and there is a substantial self-purification capacity of the river, the large amount of untreated wastewater represents a potential risk from point of view of public health. |
| Receiving Waters | In spite of the huge dilution effect, the discharge contributes to the pollution load of the river, especially from point of view of bacteriological parameters. Public Health Authorities prohibited the bathing nearly along the whole lengths of the river. The river quality deteriorates one class downstream from Budapest concerning nutrient compounds. |
| Nearby Downstream Uses | The river water is not suitable for recreational purposes because of IV class microbiological quality, partly as a consequence of the untreated wastewater discharge of Budapest (see Annex 1.). |
| Transboundary Implications | There is no direct transboundary pollution effect, due to the long distance from the downstream border section and the significant self-purification capacity of the river, however Budapest is the biggest point source emission along the whole Hungarian Danube stretch. |
| Rank | High Priority |

Table 2.16. Summary of information for the Dunaújváros municipal hot spot

| Hot Spot Name | Dunaújváros public sewer system |
| :---: | :---: |
| Critical Emissions | Considering the lack of treatment plant and the significant dilution effect of the river, special higher emission limit values were given to the system by the district Environmental Protection Inspectorate ( $\mathrm{COD}_{\mathrm{c}=}=720 \mathrm{mg} / \mathrm{l}$, $\left.\mathrm{O} \& \mathrm{G}=72 \mathrm{mg} / \mathrm{l}, \mathrm{NH}_{4}-\mathrm{N}=36 \mathrm{mg} / \mathrm{l}\right)$. The emission exceeded even these values and 0.6 million HuFt wastewater fine had to be paid last year. |
| Seasonal Variations | No characteristic seasonal change observed, concerning the quantity and quality of the wastewater collected by the public sewer system. In case of low flow conditions in the river there are still high dilution effects on the effluent. |
| Immediate Causes of Emissions | The actual cause of the emission (which is a direct point source discharge into the river) is the lack of wastewater treatment facilities. The wastewater is discharged into the river after a rough mechanical treatment (screen only). |
| Root Causes of Water Quality Problems | The Danube section, where the emission enters, carries the upstream wastewater loads. The additional load (especially the microbiological compounds) makes longer the river stretch where there are potential health risk to use the water for recreation purposes in case of direct body contacts. |
| Receiving Waters | The emission contributes to the pollution load of the river, especially from point of view of microbiological parameters, in spite of the considerable dilution effect of the river. Public Health Authorities prohibited the bathing nearly along the whole lengths of the river. The river quality belongs to the IV (polluted) quality class from point of view of nutrient compounds and microbiological parameters (see Annex 1). |
| Nearby <br> Downstream Uses | There are bank-filtered drinking water resources in operation downstream from the entering section of the emission, which are not so sensitive for the above mentioned quality change due to the filtration processes. |
| Transboundary Implications | There is no direct transboundary pollution impact, due to the long distance from the downstream border section and the significant self-purification capacity of the river, however the emission is advised to be considered in the basin-wide studies as significant direct discharge into the river |
| Rank | High priority |

Table 2.17. Summary of information for the Szolnok municipal hot spot

| Hot Spot Name | Szolnok town public sewer system |
| :--- | :--- |
| Critical Emissions | The effluent (13700 m3/d) from the town represents high emission load <br> on the river Tisza: <br> 1935 t/a COD ${ }_{\text {cr }}$ <br> 4170 t/a TDS <br> 151 t/a O\&G (oil \& grease) |
|  | Wastewater fine of 0.46 million HuFt was imposed because of exceeding <br> the existing effluent limit values. |
| Seasonal <br> Variations | No characteristic seasonal variations are observed in the quality of the <br> emission. Extremely low flow conditions of the river superimposed with <br> very high temperature usually cause additional problems in the river <br> quality downstream from the section of the effluent. |
| Immediate Causes <br> of Emissions | The basic cause of the emission is the lack of necessary wastewater <br> treatment. The wastewater is discharged into the river after a rough <br> mechanical treatment (screen only). |
| Root Causes of <br> Water <br> Quality <br> Problems | The main cause of water quality problem is the pollution impact of the <br> untreated wastewater discharged into the river. The decreased dilution <br> effect during the low flow conditions of the river usually in August cause <br> additional quality problems. |
| Receiving Waters | The quality of the receiving river Tisza deteriorates one quality class <br> downstream from entering section of the emission from Szolnok. |
| Nearby <br> Downstream Uses | There are only less sensitive agricultural water users for irrigation <br> purposes. |
| Transboundary <br> Implications | There is no direct transboundary water pollution impact from this source, <br> due to the relatively long distance from the downstream border section <br> and the existing self-purification capacity of the river, however as a <br> considerable point-like wastewater discharge into the river, it represents a <br> potential risk from this respect. |
| Rank | High priority |

Table 2.18. Summary of information for the Szeged municipal hot spot

| Name of Hot Spot | Szeged town public sewer system |
| :--- | :--- |
| Critical Emissions | The effluent (34700 m3/d) from the public sewer system of the town <br> represents high emission load on the lower section of River Tisza: <br> 5130 t/a COD cr <br> 469 t/a Oil compounds <br> $307 \mathrm{t} / \mathrm{a} \mathrm{NH}$ |
|  | No |
| No wastewater fine was imposed. |  |

Table 2.19. Summary of information for the Százhalombatta industrial hot spot

| Name of Hot Spot | Százhalombatta, MOL Rt. Oil Refinery |
| :---: | :---: |
| Critical Emissions | The regular operation of the Oil Refinery results the following concentrations in the emission into the river Danube: $\begin{array}{lc} \text { Oil compounds: } 4.7 \mathrm{mg} / \mathrm{l} \\ \text { Phenols: } & 1.0 \mathrm{mg} / \mathrm{l} \\ \text { COD }_{\mathrm{cr}}: & 133.0 \mathrm{mg} / \mathrm{l} \end{array}$ <br> Only technological failures cause essential quality problems in the river, which happened for example in October 1997 in the form of accidental oil pollution in Danube. |
| Seasonal <br> Variations | No seasonal variations in the emission. There are no wastewater discharges on holidays. |
| Immediate Causes of Emissions | The immediate cause of emission is the large amount of oily wastes (50 $000 \mathrm{~m} 3 / \mathrm{d}$ ), which first enter into a storage tank of 1000 m 3 capacity. Two stages biological treatment plant is in operation with adequate treatment efficiency. The sludge is transported away from the plant in liquid condition because locally can not be dewatered. |
| Root Causes of Water Quality Problems | Usually the effluent from the Refinery does not cause water quality problems under normal operational conditions. The breakdown of production technology however can cause significant oil pollution problem in the river. To avoid such risks the company has an effective emergency control unit to prevent potential pollution damages. |
| Receiving Waters | The treated wastewater discharge is entered into the main stream of the river. There is a considerable dilution effect of the river even during low flow periods, thus no characteristic change of river quality is observed downstream from the effluent. |
| Nearby Downstream Uses | The bank-filtered drinking water resource of the town Ercsi is in operation 0.5 km downstream from the effluent of the Refinery. No quality complaints are registered. |
| Transboundary Implications | No direct transboundary pollution impact, because of the long distance from the downstream border section, however due to the considerable amount of discharge into Danube and the potential risk of technological failures, it is advised to consider this hot spot in the further transboundary studies. |
| Rank | High priority |

Table 2.20. Summary of information for the Balatonfüzfő industrial hot spot

| Name of Hot Spot | Balatonfüzfö, NIKE Rt. Chemical Industrial Plant |
| :--- | :--- |
| Critical Emissions | The emission of the industrial plant represent high pollution load, the <br> effluent limit values is significantly exceeded in case of COD, TDS (Total <br> Dissolved Solids) and NH NH. This is why the Industrial plant was <br> imposed to an outstandingly high amount of wastewater fine of 17.9 <br> million HuFt. |
| Seasonal <br> Variations | There are no seasonal variations in the emission, there are changes only <br> within a day. The emission is more concentrated during the first shift of <br> the working day. The recipient of the wastewater discharge (biologically <br> treated) is a relatively small size creek, dilution factor is under 10. During <br> low flow period the discharge should be stored in a wastewater reservoir, <br> according to the regulation made by the District Water Authority. |
| Immediate Causes <br> of Emissions | There is an up-to-date biological wastewater treatment plant in operation, <br> but the industrial wastewater contains non-degradable chemical <br> compound in large amount. This is the basic quality problem of the <br> emission. The industrial plant carries out effective self-control activity on <br> the effluent quality. |
| Root Causes of <br> Water <br> Quality <br> Problems | The water quality problem is caused by the outstandingly high <br> concentration of pollutants in the raw wastewater, which are above the <br> effluent limit values after the treatment processes, and the low dilution <br> ratio of the recipient Veszprémi Séd Creek. The discharge from the <br> wastewater reservoir also causes quality problems along the river system. |
| Receiving Waters | The recipient Veszprémi Séd is a tributary of the Séd-Nádor river system. <br> The emission from the industrial plant deteriorates the water quality into <br> the worst V class (see Figure 4-5). The release from the wastewater <br> reservoir often causes fish kills along the river courses. |
| Nearby <br> Downstream UsesThere are different downstream water users (fishponds, irrigation <br> systems) which facing regular water quality problems. The periodical <br> release of the wastewater reservoir blocks the operation of water uses <br> along the river courses. |  |
| Transboundary <br> Implications | No direct transboundary pollution impact, however even in Danube some <br> of the non-degradable pollutants from this industrial plant can be detected. |
| Rank | High priority |

Table 2.21. Summary of information for the Kazincbarcika industrial hot spot

| Name of Hot Spot | Kazincbarcika, BorsodChem Rt. Chemical Industrial Plant |
| :--- | :--- |
| Critical Emissions | There are components in the emission of the industrial plant, which are <br> essential from point of view of pollution control: <br> TDS $=7350$ t/a <br> Na $=1650$ t/a <br> O\&G $=3.6$ t/a <br> Hg $=63.4 \mathrm{~kg} / \mathrm{a}$ |
|  | The recipient river Sajo do not provide enough dilution effect for the <br> wastewater discharge of the industrial plant |
| Seasonal <br> Variations | There is no seasonal variation, the composition of discharge is depending <br> from the actual production processes. |
| Immediate Causes <br> of Emissions | The existing biological wastewater treatment plant is overloaded, and the <br> critical emission components imply the lack of necessary industrial <br> wastewater treatment processes. |
| Root Causes of <br> Qater <br> Quality <br> Problems | The release of the high Na concentration wastewater causes problems to <br> meet effluent limit value. The material loss of obsolete production <br> technology during the past decades caused major mercury pollution of the <br> soil and groundwater resource under the area of an already abandoned unit <br> of the factory. |
| Receiving Waters | The pollutant load of the industrial plant generally does not cause major <br> water quality deterioration in the recipient river Sajó. Water quality <br> problems arise mainly in the vegetation period. The fine fraction of bottom <br> sediment of the river downstream from the effluent contains mercury in <br> concentrations of large variety because of mobility. |
| Nearby <br> Downstream Uses | Drinking water resource (Sajólád Waterworks) is in operation downstream, <br> using bank-filtered water. The applied technology of the Waterworks is not <br> sensitive for the moderate changes of river quality. |
| Transboundary | No direct transboundary impact, due to the outstandingly long distance <br> from the downstream border section of river Tisza, however as outstanding <br> industrial water user and discharger, it is advised to be considered during <br> basin-wide pollution reduction studies. |
| Implications | High priority |

## 3. Identification of Diffuse Sources of Agricultural Pollution

Nation wide database on agricultural non-point source pollution is not available in Hungary at present. Different research studies were carried out during the last decade on small size catchment areas of creeks to assess the magnitude of nutrient loads originated from agricultural land runoff (e.g.: tributaries of Lake Balaton, etc.). Nation-wide agricultural nutrient load assessments were carried out recently by two projects of the Applied Research Programme of the Environmental Programme of the Danube River basin [11.]. The EU/AR/203/91 Phare Project Water Quality Targets and Objectives for Surface Waters in the Danube Basin [12.] analyzed the nutrient immissions in the river system and made rough estimations on the proportion of nutrient load origin. For the purpose of the present Pollution Reduction Programme more detailed assessments were made in the EU/AR/102A/91 Phare Project Nutrient Balances for Danube Countries [13.], summary of the main findings are briefly discussed in paragraph 3.2 below.

### 3.1. Land under Cultivation

The land area by agricultural land-use categories in Hungary was the following in May 1997 and for comparison there are the similar values from the year 1994, as it was published by the Hungarian Central Statistical Office [9.]:

Table 3.1. Land area by agricultural land-use categories (in thousand hectares)

| Land use categories | $\mathbf{1 9 9 4}$ | $\mathbf{1 9 9 7}$ |
| :--- | ---: | ---: |
| Arable land: | 4714.4 | 4710.8 |
| Sown area | 4478.9 | 4484.1 |
| Unsown arable land | 235.5 | 226.7 |
| Garden | 35.0 | 109.2 |
| Orchard | 92.7 | 95.6 |
| Vineyard | 131.9 | 130.9 |
| Grassland | 1148.0 | 1148.1 |
| Agricultural area | $\mathbf{6 1 2 2 . 0}$ | $\mathbf{6 1 9 4 . 6}$ |
| Forest | 1766.5 | 1766.7 |
| Reeds | 40.8 | 41.3 |
| Fish-ponds | 27.2 | 33.0 |
| Productive land | $\mathbf{7 9 5 6 . 5}$ | $\mathbf{8 ~ 0 3 5 . 6}$ |
| Uncultivated area | 1346.5 | 1267.4 |
| From which: lake, water reservoir | 20.4 | 20.1 |
| Land area total: | $\mathbf{9 3 0 3 . 0}$ | $\mathbf{9 3 0 3 . 0}$ |

The usage of fertilizers (as a factor of agricultural non-point source pollution) decreased significantly during the last decades [2.]. The gross agricultural production shows somewhat similar tendency, as it is illustrated in Table 3.2. Data contained in this Table were published in the volumes of the Annual Statistical Yearbooks [9.].

Table 3.2. Agricultural production and fertilizer usage

| Years | $\mathbf{1 9 8 0}$ | $\mathbf{1 9 9 0}$ | $\mathbf{1 9 9 4}$ | $\mathbf{1 9 9 5}$ | $\mathbf{1 9 9 6}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Relative volume index of the total agricultural <br> production (basis: $1980=100 \%$ ) | 100.0 | 101.4 | 71.0 | 72.6 | 76.2 |
| Total use of fertilizers, in <br> Effective material, 1000 tons/year | 1399 | 671 | 280 | 247 | 270 |

### 3.2. Diffuse Nutrient Emissions from the Agriculture

The EU/AR/102A/91 Phare Project Nutrient Balances for Danube Countries" [13.] carried out studies on national and Danube basin level on the magnitude and proportion of diffuse nutrient load compared to the total loads.
The investigation of the sources and pathways of nitrogen (considering the data from 1992) resulted in the conclusion on river basin level, that the importance of agriculture for N emissions into surface waters is evident: about half of the input stems from agriculture. The two main paths, runoff and base flow have the same importance, each carrying one third of the agricultural N emission. The contribution of private households to the input is about $20 \%$, while industry represents $10 \%$ and other sources about $20 \%$. For phosphorus the importance of agriculture is even greater, clearly showing that when developing future emission reduction strategies agriculture will play a key role. Almost $60 \%$ of the total P stemmed from agriculture. Herein, the paths erosion/runoff (about half of the agricultural emissions) and direct discharges of manure (about one third) should be underlined. Private households contributed to about $20 \%$ and industry was about $15 \%$ (the others were below $10 \%$ ).
Out of the total inputs in the Danube basin, about $60 \%$ of N and $40 \%$ of P stemmed from diffuse sources, according to the findings of this project. This ratio shows a similar pattern valid for many river basins in Europe. Base flow, erosion/runoff, runoff from forests stormwater overflow and N fixation was accounted for these assessment. The complementary values indicate point source contribution (wastewater effluents, direct discharges from households, industry and manure). The national patterns were also developed [13.], of which the relevant values for Hungary are given in Table 3.3.

Table 3.3. Nutrient emissions from diffuse and point sources in Hungary Source: Phare Project EU/AR/102A/91 [13.]

| Origin of nutrient <br> emissions | Total Nitrogen in kt /a |  |  | Total Phosphorus in kt |  |
| :--- | :--- | :--- | :--- | :--- | :---: |
|  | $1988 / 89$ | 1992 | $1988 / 89$ | 1992 |  |
| Diffuse sources | 88 | 53 | 7 | 7 |  |
| \% of the total load | 71 | 62 | 42 | 42 |  |
| Point sources | 37 | 32 | 10 | 10 |  |
| \% of the total load | 29 | 38 | 58 | 58 |  |

## 4. Updating and Validation of Water Quality Data

Water resources management has an outstandingly long tradition in Hungary. Observations and data collection on the quantity and quality of the surface water resources were always considered as important activities to assist the water management efforts.

## Hydrological (water quantity) observations

Records of extreme hydrological events were preserved for the period before the 18 -th century (e.g. the report of the first flood on the river Danube dates back to 1012). Extensive survey of watercourses started in the 18 -th century. Beside hydrographic works, level/flow gauges were built in large cities of the Kingdom of Hungary in Pozsony/Pressburg (today Bratislava) and in Buda (today Budapest). Regular observation of water levels started in 1823. An observation network of 132 gauges was in operation in 1860, where water stages together with ice phenomena were observed on a daily frequency. Measurement of water temperatures started in 1865 with special regard towards the formation of ice jams. Operational water level data had been distributed during floods in the Tisza basin since 1856 for a large circle of interested agencies and authorities.
An important milestone in the development of observations over surface waters was the organization of a Central Hydrological Unit in the year 1886. This institution was one of the firsts of its kind in Europe. Regular hydrographic surveys of river channels were also organized. While stations of the observation network remained in the hands of local authorities, techniques and instrumentation were standardized. In addition, nation-wide supervision of activities was organized together with the formation of the national hydrological archives and the national hydrological forecasting service. Hydrological yearbooks have been issued since that time. Publishing of the Daily Water Regime Map started as a result of daily (and in the period of floods more frequent) collection of data from basic stations.

A new phase in water resources development started in the 1930's (irrigation, fisheries, industrial water use in large scale). Accordingly regular flow measurements and registration started (the first flow measurements however were attempted much earlier, already at the beginning of the 19-th century). Flow measurements on medium size rivers started in the 1930's and on small steams from 1950. Together with the construction of barrages and reservoirs measurements on suspended sediment started. Operational observations and data collection covered reservoirs and large water distribution systems.

Regular observations of subsurface waters started around 1930 in the interfluvial region, Danube Tisza, and from 1950 groundwater level observations covered the whole country. Observation of springs also started around 1950 together with karstic water level observations. Organization of the observation of deep groundwater and thermal waters was the task of the following decades. Observation wells are the former boreholes of exploration drillings and also many former production wells are used in the network [14.].

## Water quality observations

The history of the measurement of water quality of Hungarian surface waters dates back to more than a century ago. The first published measurement data stem from 1873 when the water quality of the river Danube was discussed in terms of the cations and anions found in the river water. Only few publications are known from the first decades of the 20-th century. The need of the society for investigating the quality of waters occurred first upon the extensive industrialization after the Second World War. In the beginning, however, no overall scheme of these investigations was established and the measurements were limited to some special problems of individual watercourses.

The Water Resources Research Institute VITUKI made plans for the establishment of a nation wide water quality monitoring system right in the year of its establishment, in 1952. At this time, however, VITUKI did not have its own water chemical laboratory and the analytical work was carried out in MÉLYÉPTERV. Nevertheless, sampling and evaluation work was made in the water quality management department of VITUKI, founded in 1954. On the basis of the publications of this early period it can be concluded that VITUKI had made measurements in 1,400 stations of 130 streams and for 25 water quality constituents. The frequency of the random samplings was once a year. It is worthwhile to mention that the water quality parameters investigated in those times are still being measured today.
The above mentioned and published data are important sources of information on the water quality conditions of an era more than 40 years ago. Eventually there is no basis of full comparison with the presently measured data, due to the substantial development of analytical methods (for example those for nitrate and orthophosphate) since that time.

Development of the laboratory network of the district water authorities started in 1956 on the basis of the professional knowledge available in VITUKI. The work of these laboratories involved, in the early times, large number of stations (appr. 800) and low sampling frequency (about 4 samples/year). It took some years until the 12 district water authorities had more-or-less well equipped water quality laboratories and appropriately qualified staff.
Between 1960 and 1967 the district water authorities operated about 800 water quality monitoring stations on 290 streams and the supervision of the system was carried out by VITUKI. The frequency of sampling was 2-12 in a year. In about $60 \%$ of the stations the sampling was seasonally made ( 4 samples in a year). Random schedule was followed during the lowest frequency samplings (twice a year). Laboratory analysis involved $15-30$ water quality constituents and indices.
Preliminary evaluation of the large number of data available for the period 1960-1967 indicated that the increasing of the frequency of sampling would be desirable, even at the expense of sacrificing some of the less important monitoring stations. Results of weekly sampling of the river Danube also indicated that this was the right solution.
Upon the proposal of VITUKI new sampling rules have been put into force in 1968. In this new network and system the number of stations was reduced to about 300 and the sampling frequency increased to 12 annually as the minimum. This way was the basic national water quality monitoring network (called national network further on) founded. Some stations started in 1968 and other ones in 1969 and they were operated in this form until 1984. The national network involved the 113 most important watercourses of the country, the analysis of appr. 50 water quality parameters and sampling frequencies of annually 12,26 and 52 per year ( 108 samples per year in a single station). It is of importance that in this period the analytical methods were also internationally harmonized (within the so-called COMECON countries the harmonization was made on the basis of the Standard Methods of the USA).
The objective of the national network was to:
> obtain insight into the state and expectable changes of the water quality of the surface water resources of Hungary and
> to help various water users in assessing the options of using the given water for the desired purposes.

Requirements for the operation of the national network were as follows:
$>$ to provide sufficient number of data for evaluating the quality of waters in a general way and also according to intended water uses and to follow the changes of water quality;
$>$ to support transboundary water negotiations and to provide appropriate time series for research and planning.

The national network was operated in the above described manner between 1968 and 1984. New monitoring rules were established in 1985. This included 250 stations and the sampling frequency was 52,26 and 12 . This provided continuity of records for the bulk of the stations.

The sampling stations were selected to meet the following requirements:
$>$ Entrance and exit stations of rivers entering and leaving the country;
$>$ Upstream and downstream of significant sources of pollution that could basically alter the quality of water;
$>$ At especially important sites (such as the water intake points of the waterworks).
The rules of sampling and the type of water quality parameters were defined by technical guidelines (MI-10-172/2-84 and MI-10-172/3-85). The evaluation system included three classes (not given in detail here) as specified in Hungarian Standard MSz-10-172/1-83.

The present water quality monitoring network has been in operation since 1994. Details of the operation (sampling sites, sampling frequency, analytical frequency, groups of water quality indices, analytical methods, methods of evaluation/classification and the system of limit values) are specified in a national standard (MSz 12749) [4.].

### 4.1. Index of Water Quality Monitoring Records

The results of the existing monitoring activities of surface water resources are briefly summarized in this chapter, covering the quantitative (hydrological observations) and the qualitative (water quality monitoring) aspects. The topic of accidental water pollution incidents is also included.

### 4.1.1. Data Coming from the Hydrological Observation Network

The existing hydrological surface water observation network to monitor the quantitative characteristics of the river system in Hungary consists of 2700 stations, of which 370 are considered to be basic stations.

Stations of the basic network have been selected on cross boundary rivers/streams near the national borders. Basic stations are designated to each other in $20-30 \mathrm{~km}$ sections of major rivers, reservoirs, and large lakes, or one station for each $400-500 \mathrm{~km}^{2}$ of territory in case of small streams and canals. Water levels are observed at each basic station together with ice phenomena. Thickness of the ice cover is measured on rivers with the formation of ice jams and on larger lakes. Flow rate is measured and registered at 185 stations, water temperatures at 87 stations and suspended sediment at 37 stations.
The network diagrams of the river system are illustrated in Figure 4.1. (Danube and its tributaries) and in Figure 4.2. (Tisza and its tributaries). These Figures give information also on the type of hydrological observation stations in operation in that region and the frequency of data reporting from that station [15.]. The locations of the main hydrological observation stations (stations of the national hydrological telemetry network) are shown in Figure 4.3.

The groundwater observation network consists of around 1600 observation wells, there are 500 karstic water and deep groundwater observation wells and around 50 springs are observed.

The tasks of the hydrological service are carried out by the 12 District Water Authorities and the Water Resources Research Center VITUKI Plc. The District Water Authorities are working under guidance of the National Water Authority (OVF) and VITUKI carries out central functions of the hydrological service on the basis of a contract with OVF. Supervision of the given scope of activities at the level of the national government is realized through the Ministry of Transport, Communication, and Water Management (KHVM). Tasks and functions within the hydrological
service are divided among the players by relevant legislation and directives, which are to be changed in the near future. Legislation enforces reporting of water supply data to regional water authorities for all water uses. The hydrological service works in cooperation with different agencies of environmental protection and with the National Meteorological Service.

Unfavorable aspect for water management in Hungary is that approximately $95 \%$ of the surface water resources originate from abroad. This means that special attention is paid to the border sections of rivers entering into the country, not to speak about the fact, that some of them carry significant pollution load from abroad. For information on the size of these rivers Table 4.1. summarizes the daily flow condition data observed during the period between 1985 and 1994.

Table 4.1. Flow-data in the border-sections of transboundary rivers (1985-1994)

The above Table illustrates the mean flow (KÖQ) values of the transboundary rivers related to the 10 years period, and for additional information there are the observed smallest (KQ) and highest (NQ) flows of this decade. Time-series of flow data were not available for smaller rivers. The column „Name of Section" contains two names when the water quality observation (sampling) differs from the hydrological observation site. There is a straight requirement however to carry out quantity and quality observations in the same section to improve the information content of the observations. The identification codes and the measurement/sampling sites of these rivers are given in Table 4.2.

Figure 4.2. Network diagram of the river system in Hungary River Tisza and its tributaries

### 4.1.2. Data Coming from the Routine Water Quality Monitoring

The national water quality monitoring network is in operation at present according to the requirements of the relevant Hungarian Standard MSZ 12749 [4.] and consists of 150 sampling stations. The Standard precisely regulates the requirements and conditions of the routine water quality monitoring activities and contains the following main issues:
> list of sampling sites on rivers, main canals, lakes and reservoirs,
$>$ frequency of samplings (Table 4.3.),
> list of quality parameters to be determined in each sampling sites,
> surface water quality standards (see Annex 1.),
> classification system, and
> method of preparing water quality maps.
Novelty of the monitoring system in operation since 1994 is the complexity, the evaluation and processing of quality data and covers also the results of the microbiological investigations carried out by the cooperating partners within the public health sector. Locations of the important water quality monitoring stations are illustrated in Figure 4.4.

Table 4.3. Sampling frequencies in the national monitoring system

| River <br> System |  |  |  |  |  |  |  | Total |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{5 2}$ | $\mathbf{2 6}$ | $\mathbf{3 x 2 6}$ | $\mathbf{2 4}$ | $\mathbf{1 2}$ | $\mathbf{8}$ | $\mathbf{6}$ |  |
|  |  |  |  |  |  |  |  |  |
| Danube | 8 | 65 | 6 | 6 | 3 | 0 | 6 | 94 |
| Tisza | 8 | 43 | 1 | 0 | 0 | 4 | 0 | 56 |
| Total | 16 | 108 | 7 | 6 | 3 | 4 | 6 | 150 |

The national water quality monitoring network is supplemented by a regional network with further 91 stations, data of which are also processed together with the data coming from the national network.

The up-to-date on-line connection between the laboratories of the Environmental Protection Inspectorates (which took over this task from the district water authorities) and the Institute of Environmental Management (KGI), where the data processing is made, is still lacking. The form of data transfer is still the sending of floppy diskettes. The Environmental Protection Inspectorates are to send the monthly records to KGI by the middle of the next month.

## Publishing of the water quality data

The Institute of Water Management VGI, predecessor of KGI, regularly published the data in annual Water Quality Year Books in the period 1970-1981. Volume 11 of this series, for example, includes (among others) the statistical evaluation of the 1976-1978 data of 95 stations: annual minimum, maximum and mean, standard deviation, annual median, summer half-year average and classification on the basis of limit values of the prevailing standard, $90 \%, 80 \%$ and $10 \%$ duration values. The tabulated summary was made for the following parameters: $\mathrm{COD}_{\mathrm{d}}, \mathrm{BOD}_{5}, \mathrm{DO}$, TDS, $\mathrm{NH}_{4}, \mathrm{NO}_{3}$ and extracted (UV) oil.

The series of Water Quality Year Books was terminated in 1981 and was replaced by a new series "The Quality of Waters in Hungary", which is being still published annually, with a one year time lag. The volume, rich in tables and figures and evaluating texts can be considered an outstanding and important source of information even in international relation. The latest volume was published in 1997 containing information on the situation in 1996 [5.].

Similarly the VGI/KGI has annually published since 1970 the overall water quality maps of Hungary. The maps show the water quality classes and critical values on the basis of the relevant Hungarian standards of the period of concern (MSz-10-172/1-83 and MSz 12749).

## The computer software system of the water quality data base

The publications mentioned above serve, in spite of their information richness, mostly for supporting the work of higher level decision makers. The blast-like propagation of PCs in Hungary made the water quality database accessible for many users. In this respect the computer software system termed "Collection and processing of surface water quality data" should be mentioned. This system is being developed in VITUKI in an MS WINDOWS version and will be available by the fall of 1998 for nation wide distribution. The hardware requirements are, as minimum, a 486 processor, 16 MB RAM, SVGA monitor and a relatively fast printer (such as HP 4L).
In the main menu of the system the following initial settings can be made: monitoring stations (and the saving of them), components (and their saving), period to be processed, months to be included, filter values for any water quality parameter, relations ( $<, \leq,>, \geq,=, \neq$ ), operations (printing, exporting to EXCEL, etc). The present version of the software offers the following functions:
$>$ Entering measurement data
$>$ Visualization of measured values
> Basic statistics
> Basic statistics in annual distribution
> Basic statistics in monthly distribution
$>$ Linear trend analysis
> Water quality classification
$>$ Export of basic data to EXCEL
$>$ Data supply for other agencies (KGI, ANTSZ)
$>$ Listing of measurement data
$>$ Preparation of tables of content
$>$ Visualization of the results of a single investigation for each records
$>$ Tables of duration values
The term "basic statistics" means in this case: number of measurements, minimum, maximum, mean, standard deviation, variance, $10 \%, 90 \%$ and $95 \%$ duration values.

Figure 4.4. Sampling stations of water courses and lakes

## Water quality classification system

The monitoring systems of 1984 and 1994 (and the standards behind them MSz-10-172/1-83 and MSz 12749 respectively) differ from each other in three aspects:
> The qualification system, which came into force in 1985, was based on various water uses (biological stability, drinking water supply industrial water supply, irrigation, fisheries and integrated requirements), while that of 1994 is focused at the water as an ecological unit, disregarding water uses. Instead of this latter different groups of components are specified (Annex 1) The difference is only virtual since the integrated qualification system of the former actually includes the quality indices of all water uses and the limit value system is the corresponding range. The latter cannot be used for qualifying according to water uses. In respect to the second the original concept was that as a continuation of MSz 12749, which was developed by the environmental ministry KTM, another system will be developed by the ministry for water management (KHVM) focusing solely at qualification according to water uses. This latter has not yet been done. According to the available information the ministry KTM will again give a contract for the development of a new system.
> In the system of 1985 the basis of the classification is the $80 \%$ duration value (the $80 \%$ percentile), while in that of 1994 the $90 \%$ value (that is a value which is closer to the measured maximum than in the case of the former one). It is to be noted that in case of fewer than 10 samples the determination of these percentiles is not allowed by the rules of statistics. In this case we usually apply the measured maximum, marking this in a footnote.
> The standard of 1994 has substantially expanded the scope of the measured parameters (Annex 1).

Both systems classify for each of the components. In the first system the quality class was defined on the basis of the worst component. In the second system the classification is made for component groups, also on the basis of the worst component of that group.

For the purpose of transboundary studies on water quality conditions, it is important to have information regarding the number of samples (frequencies of sampling) at the different stations and also on the frequency of analytical determinations of certain special water quality parameters.
The Tables (which are attached as Annexes) prepared for this purpose correspond to the nearborder stations of the most important transboundary rivers of Hungary and to the mouth stations of three rivers whose catchments fall entirely to Hungarian territory. Annex 2.3. shows the number of samples for the period 1968-1997, separately for the Danube and Tisza River systems. Annex 4.5. presents the number of water quality analyses, also for the two larger catchments, but only for the year 1997. For the traditional components $\left(\mathrm{COD}_{\mathrm{d}}, \mathrm{COD}_{\mathrm{p}}, \mathrm{BOD}_{5} \mathrm{NH}_{4}-\mathrm{N}, \mathrm{NO}_{2}-\mathrm{N}, \mathrm{NO}_{3}-\mathrm{N}\right.$, mineralN and $\mathrm{PO}_{4}-\mathrm{P}$ ) the sampling frequency does not considerably differs from the analytical frequency. The analytical frequency of special components measured since 1994 can be well estimated on the basis of data given for 1997 [16.].
Water quality classification was made on the basis of Hungarian Standard MSz 12749 for the stations listed in Annex 2.3. Resulting $90 \%$ duration values are in Annex 6.7. while the classes are shown in Annex 8.9. Data of these tables are self-explanatory ones and only some additional remarks will be given below:
$>$ In order to facilitate lucidity water quality class $\boldsymbol{I} \boldsymbol{V}$ are given in bold italic while class $\boldsymbol{V}$ in bold italic underlined.
> Comparing the water systems of the rivers Danube and Tisza it can be concluded that the water quality of the former is generally better.
> In Danube system the worst conditions were observed in the Szekszárd-Palánk station of the Canal Sió. In case of microbiological parameters the worst condition was observed at the Dunaföldvár station of the river Danube, indicating the pollution effect of Budapest. In case of inorganic micropollutants the Györzámoly station of the river Danube was the worst, showing the effects of the inadequately treated wastewaters of the industrial region along the river Morava.
> In Tisza water system the least satisfactory situation was observed in station Mérk of the river Kraszna. Exceptions are: the heavy metals for which the Station Csenger of the river Szamos was the most polluted one, well characterizing the shortcomings of industrial wastewater treatment in the Rumanian drainage basin.
> It should be mentioned that in the Danube water system the cleanest station was Drávaszabolcs of the river Dráva, while in the Tisza water system the Tiszabecs station of the river Tisza was the least polluted one.
$>$ Comparing component groups to each other the most unfavorable group was that of the microbiological parameters, well characterizing the conditions of communal sewage treatment in some of our upstream neighbor countries.
> Regarding organic micropollutants it should be mentioned, in the light of the data of Annex 4.5. that only scattered data area available and the field laboratories are still in the phase of training. Exceptions are mineral oil products, phenols and ANA detergents.
$>$ Of the parameters of radioactivity satisfactory data are available for beta-activity only.
$>$ Regarding iron and manganese it should be mentioned that occasionally observed unfavorable conditions are due mostly to natural, geochemical, factors and not to anthropogenic impacts.
> Anions and cations are not shown in the tables. Hungarian standard MSz 12749 requests monthly measurement of these parameters but does not specify limit values. Their evaluation and classification can be made in terms of conductivity, which is proportional to total dissolved solids.
> Finally it should be emphasized that the data presented correspond to a ten-year period (1988-1997). Water quality changes, which have occurred in the meantime, will be discussed in the next section.

The latest water quality map of the Hungarian river system is illustrated in Figure 4.5.

## Tendency of water quality changes

To assess the changes and water quality linear trend analysis were made for the stations discussed in previously for the ten-year period of 1988-1997. Results of this analysis are shown in Table 4.4. and Table 4.5., according to the water systems of the rivers Danube and Tisza. Results of the calculation are presented in \%/year dimension.

In selecting the period the basic concept was that this is the period when substantial economic recession was experienced in both Hungary and in some of our upstream neighbors (while in other upstream neighbor countries this was the period of large scale development of sewerage and sewage treatment). Both resulted in substantial decrease of pollution loads. To illustrate this we mention here only a single numerical date: in 1994 in Hungary the total of nitrogen fertilizer application rate was as low as in 1960 and was about one-third of the maximum rate of 1988.

Table 4.4. Tendency of quality changes in selected river sections (Danube catchment)

### 4.1.3. Data on Accidental Water Pollution Incidents

Approximately $95 \%$ of the surface water resources originate from abroad. This condition creates a continuous potential risk for water users principally from the point of view of quality, but also of quantity. In particular, the safety of drinking water intakes is endangered, because the river systems entering Hungary are often subjected to accidental water pollution incidents. An actual need has been formulated during the recent decade by the Waterworks using surface water resources for public drinking water supply towards early warning services, which can increase the safety of their operation by providing information in due time about the characteristics of an unexpected accidental water pollution event. There are no early warning water quality monitoring systems in operation at present in Hungary, except the international Danube Accident Emergency Warning System (Danube AEWS). One of the main goals of a recently completed Phare project ("Development of surface water monitoring based on the EU practice in Hungary") in this field [14.] was to evaluate the existing data and information from this respect and create a practical basis for the future implementation of early warning systems. On the other hand Hungary actively participates in the operation of the Danube AEWS, having the fully operational Hungarian National Center of this Danube AEWS in Budapest called PIAC-05 (Principal International Alert Center).

The regular surface water quality monitoring network has 27 sampling sites on rivers crossing the national borders of Hungary, of which there are 24 sites of entering sections and only 3 sites of leaving sections. This situation underlines the importance of water quality control at the border sections of the river-system, with special attention on sudden changes of quality caused by accidental river pollution incidents abroad. Figure 4.7. illustrates the river system of Hungary with special attention on the transboundary rivers arriving from upstream countries, and based on a former study [18.] the distribution of foreign accidental water pollution incidents are also introduced.

Figure 4.6. Accidental water pollution incidents in Hungary between 1985-1986

Figure 4.7. The river system of Hungary and statistics on transboundary water pollution incidents

Figure 4.5. Water quality map of the river system in Hungary, 1997

Accidental water pollution incidents registered on national level by the responsible Hungarian Authorities (the 12 district Environmental Protection Inspectorates) are summarized in Figure 4.6., illustrating the number of pollution cases originated both from domestic and foreign sources between 1985 and 1996. The culmination of the numbers of pollution incidents has occurred in 1987, when there were 262 cases, of which 208 affected surface waters within the country and 31 arrived from upstream foreign countries [17.]. The polluted water travelled down on the rivers to Hungary and caused temporary problems in the use of river water. Following the year 1987 the observed annual number of accidental water pollution events generally decreased, and since 1991 a significant decrease of cases was observed. It is necessary to note, that the basic cause of this change is assumed to be the recession of economies of the countries upstream from Hungary, resulting in decreased industrial activities, less usage of agrochemicals in the agriculture, etc.
The results of the regular water quality monitoring usually can not reflect the unfavorable effects of accidental pollution events, which basically have a stochastic character. This is why the automatic water quality monitoring stations have outstanding importance in border sections of those rivers, which are often subjects to accidental water pollution originated abroad.
The analysis of the distribution of the type and kind of observed accidental water pollution events showed that mineral oil and its products coming from different sources were responsible for most of the pollution events in each of the years. Pollution from source indicated as "industry" organic and inorganic industrial wastes were reported, from "agriculture" generally land runoffs polluted by fertilizers and pesticides and accidental discharges from animal husbandries were observed, while as "other" sources different specific pollution incidents were summarized, like algae blooms (increased rate of primary production), etc.
According to the results of a previous study based on the available data on the ten years period between 1981 and 1990, accidental water pollution events endangered drinking water resources, resulting in restrictions on, or even the shut-down of surface water intakes in 26 cases during this period. There were also temporary closures of intakes on five occasions for periods longer than two days. Events of special interest were related to an increased rate of primary production (algae blooms), that had paralyzed the operation of the Surface Water Intake Works of the Budapest Waterworks on four occasions [18.].

A significant number of the accidental river pollution cases were caused by oil-spills from different sources during the last ten years. The Danube-Maine-Rhine waterway, after being put into operation, may be exposed to an increase in oil pollution, which may also affect the Hungarian stretch of the river Danube, where the safety of drinking water resources is outstandingly important from point of view of public supply.
There is a nation-wide watching and observation system of the environment protection and the water management sectors to detect accidental water pollutions, assisted by public organizations (e.g.: angling societies, etc.) as well as state organizations, like Water Police, Home Guard, etc. The separation of the formerly unified water and environment protection sector in 1990 however significantly weakened the efficiency of the formerly common and unified activities in this field.

## The Danube Accident Emergency Warning System (DAEWS)

The objective to establish the DAEWS was to increase the safety of the population and to protect drinking water resources in particular, should accidents occur which have a negative impact on the Danube River or its tributaries, and to protect the environment against the effects of such incidents. Especially in case of water pollution incidents having transboundary character there is a clear need to improve the flow of early information about such events between the riparian countries. In the present phase the DAEWS deals first of all with transboundary water pollution problems, and able also to assist flood control activity by providing rapid information on unexpected changes of water levels. Later the fields of activity of the system can be extended to any kind of environmental hazards or catastrophic events [19.].

The development work of the regional DAEWS system has been designed and carried out by the Accident Emergency Warning System Sub-Group (composed of experts from the riparian countries). Delft Hydraulics as Consultant partner provided technical support for the development activities and the Danube Program Coordination Unit in Vienna carried out coordinative assistance for this work between the years 1992 and 1997.

The practical experiences gained in the many year's operation of the international Rhine Alarm System and also the recently developed system for the Elbe River have been the basis for the proposed set-up of the DAEWS. Activities are still going on, focussed mainly on the preparation of the field implementation of the system in the riparian countries. An essential feature of the set-up of the DAEWS is that it is in accordance with the relevant and adopted multilateral conventions and declarations, as well as on the existing bilateral agreements between the neighboring countries of the River Basin.

The DAEWS consists of three basic elements:
$>$ the National Centers which are already established in the riparian countries, called Principal International Alert Centers (PIAC-s);
> the international satellite communication system between the PIACs, and
> the supporting institutional background in each country.
The basic role of the PIACs is to coordinate emergency warning at international level. Participating countries already nominated the locations of these Centers, which are forming the backbone of the system. The location of the PIACs in the Danube River basin is illustrated in Figure 4.8.

There is a territorial "gap" in the system for the time being, represented by the countries of Yugoslavia and Bosnia-Herzegovina. The design of the DAEWS however easily allows the extension of the system in the future, with an integration of the remaining areas in the region. The PIACs of Ukraine and Moldova are under establishment by the financial assistance of the Tacis Fund.

The basic role of the PIACs is to coordinate emergency warning at international level. In case of an accidental spill an early message (or warning if there is serious water quality deterioration observed) is transmitted towards the downstream with detailed information on the characteristics and expected effects of the pollution. Information provided in due time by the PIACs could substantially support the pollution control activities of the responsible local authorities of the riparian countries and could prevent possible damages, or operational problems at the important water users.

To perform these tasks there are three units at each PIAC which closely cooperate in case of emergencies:
$>$ the Communication Unit: $C U$ (receiving and handling messages through the satellite communication system without delay, working on a 24 hours basis),
> the Expert Unit: EU (assessing the transboundary effects or impacts of a reported accidental pollution, this activity is supported by the use of the data-bank on dangerous chemical substances and the Danube Basin Alarm Model), and
$>$ the Decision-making Unit: $D U$ (licensed with authority to make decisions on local, or international warnings).

International Operation Manual ensures the smooth and unambiguous operation of the system. Standard Message Forms were developed for the international communication to be used for warning, information request, confirmation of messages, or end of alert messages. The language of the international communication via satellite is English, but the arriving messages are automatically translated into the national language at each PIAC by the applied Information Processing System.

Figure 4.8. The location of the PIACs of the Danube AEWS

The Hungarian PIAC-05 is located in Budapest and its Communication and Expert Unit is situated in the Water Resources Research Center VITUKI Plc. The Hydrological Forecasting Center deals with the tasks of the Communication Unit, dealing with flood forecasting operations and maintaining all day duty. The Expert Unit works at the Institute for Water Pollution Control, where the Central Water Quality Laboratory can assist this activity with high level analytical instrumentation. The Decision Making Unit is in the Ministry of Environment and Regional Policy (KTM) where the Department of Environmental Safety has this responsibility. There is an on-line computer system to support the activities of the three Units in case of emergency situations. The set-up and the institutional background and the communication lines (local Environmental Protection Inspectorates: KF, and Water Authorities: VIZIG) are illustrated in Figure 4.9.

Figure 4.9. Set-up of the Hungarian PIAC-05 of the Danube AEWS

The local Environmental Protection Inspectorates use the Hungarian versions of the Standard Message Forms to send immediate information to the PIAC about detected accidental water pollution incidents. Recently (October 1997 and May 1998) the Hungarian PIAC sent two times international warnings to downstream countries for information on Danube pollution occurred in Hungary, however none of these cases resulted later in transboundary pollution impacts and thus end of alert messages were sent to the same addressees.

### 4.2. Data Quality Control and Quality Assurance

The importance of reliable and correct control of data for water quality/pollution monitoring is internationally recognized. The quality control of data coming from the regular monitoring activities are running in two main areas. The first is the analytical quality control, which is particularly important in the monitoring of river systems when several laboratories are participating in the water quality monitoring programs, and especially in case of international rivers, when laboratories from different countries are involved. The other area is the data quality control, when the reliability, consistency and compatibility of the data elements are controlled. This activity is discussed in chapter 4.3.

### 4.2.1. Analytical Quality Control and Quality Assurance in Hungary

The analytical quality control ( QC ) using check samples for interlaboratory comparison among the laboratories of the Hungarian District Water Authorities started in early 1970s and was initiated by the Water Quality Department of VITUKI. In 1974 VITUKI organized, in collaboration with the Danish Water Quality Institute and the German Emmscher-Genossenschaft, interlaboratory comparison exercise among European water laboratories as part of a programme by WHO Regional Office for Europe. VITUKI continued the proficiency testing in Hungary among the laboratories of the Environmental Protection Inspectorates when they were established from the District Water Authorities in the mid 1980s and soon later extended the check sample distribution to the laboratories of the water works and wastewater treatment plants. At present the number of participating laboratories exceeds 130 within the country.

The QualcoDanube intercalibration program for the Hungarian laboratories includes the quality control of analytical determinations carried out from drinking water, surface water, wastewater, bottom sediment and sludge samples. The quality parameters covered are general parameters, nutrients, heavy metals and non-specific parameters (BOD, COD, ANA-detergents). The applied methods, distribution of samples, statistical processing and evaluation of results are regularly discussed in details in the relevant reports of VITUKI [20.]. The participating laboratories provided successful results in the determination of heavy metals and general parameters, among nutrients the nitrite. Improvement was observed in case of ammonium compared to previous years, while in case of BOD the results were not good.
The process of accrediting the Hungarian analytical laboratories in the field of water and environmental quality control has begun in 1995/96 and a three years' license is given to laboratories meeting the very strict requirements as stated in the Hungarian Standard MSZ EN 45001.

### 4.2.2. Analytical Quality Control and Quality Assurance on International Level

The need for interlaboratory comparison studies in the Bucharest Declaration Danube monitoring was discussed during the $5^{\text {th }}$ expert meeting in October 1992, held in Bucharest. This meeting agreed to organize an interlaboratory comparative exercise in 1993. The Institute for Water Pollution Control of VITUKI, Budapest, Hungary, took responsibility for organizing the first laboratory comparative runs under the name of QualcoDanube. As part of the AQC for the Bucharest Declaration monitoring, the first distribution in 1993 of samples for analysis included three determinants: pH , conductivity and total hardness. By the end of 1995, four more distributions had been made for analysis of the following determinants: chlorides, COD, nutrients (ammonium, nitrate, Kjeldahl-nitrogen, orthophosphate and total-P) as well as different metals, including $\mathrm{Fe}, \mathrm{Mn}, \mathrm{Ca}, \mathrm{Mg}, \mathrm{Cd}, \mathrm{Cu}, \mathrm{Hg}, \mathrm{Pb}, \mathrm{Ni}, \mathrm{Zn}$. By the end of 1995 five distributions had been conducted.
The Monitoring, Laboratory and Information Management Sub-Group (MLIM-SG) of the Environmental Programme for the Danube River Basin have discussed the problems of quality assurance and analytical quality control (AQC). In 1995 the QualcoDanube proficiency testing scheme was extended to the National Reference Laboratories (NRL) in the Trans-National Monitoring Network (TNMN) and the 1996/2 distribution already included all Danubian laboratories - 11 NRLs and 18 national laboratories - implementing the monitoring programme.
The QualcoDanube distribution 1996/3 was further extended to the Black Sea laboratories (seven) responsible for pollution monitoring in their area. Seven of the Hungarian District Environmental Inspectorates (No. 1, 2, 3, 4, 5, 8 and 11, location of them is illustrated on Figure 2.1.) are also participating in this international intercalibration programme and among them there are the three Inspectorates working along the Hungarian stretch of Danube. This is an important factor from point of view of providing harmonized water quality data for basin-wide studies.

In 1996 four distributions had been made for analysis of general parameters, nutrients, heavy metals and organic pollutants. In 1997 four distributions had been made, too. Most of the determinants were the same as in 1996, but for the first time petroleum hydrocarbon extracts among organic pollutants - were also distributed. The type of samples and determinants are listed in Table 4.6.
The Institute for Water pollution Control of VITUKI annually evaluated the results of the QualcoDanube intercalibration programme [21.]. Most of the data provided by the laboratories during the 1997 intercalibration study were satisfactory, when comparing to error thresholds.

While the results in 1996 showed the quality improvement in most of the determinants, in 1997 continuous improvement could not be observed. The performance for the general parameters was satisfactory. Some problems arose due to stability of the samples (e.g. MBAS, $\mathrm{PO}_{4}-\mathrm{P}$ ) and a relatively long analysis time, which can influence the variation between results.

In case of metals different digestion methods were used and there were some problems for less commonly measured metals (e.g. $\mathrm{Hg}, \mathrm{As}$ ) and at low concentration level (e.g. $\mathrm{Cd}, \mathrm{Ni}, \mathrm{Pb}$ ).
Interlaboratory studies organized regularly help to improve analytical performances because the participants can review their own performance concerning the accuracy of the analytical results and where necessary, investigate the sources of error and take corrective actions.
So, it is expected that performance of the Danube basin laboratories will further improve and the comparability of the water quality monitoring results in the river basin and related regions will be ensured.

Table 4.6. Type of samples and determinants in the QualcoDanube check sample scheme

| Determinant | G | N | HM | ORG |

### 4.3. Data Consistency, Compatibility and Transparency

The results of the national water quality monitoring activities are centrally controlled and processed at the Institute of Environmental Management (KGI). The up-to-date on-line connection between the field laboratories of the Environmental Protection Inspectorates and the Institute is still lacking. The form of data transfer is still the sending of floppy diskettes. The Environmental Protection Inspectorates are to send the monthly records to KGI by the middle of the next month. This is followed by the routine validity checking there.

Essentially the checking includes comparison to a pair of limit values, which are being defined statistically for each station on the basis of the measurement data of the previous 3 years. A list of potential error is generated on the basis of this comparison for the "suspicious" data. These suspicious data are checked by the experts of KGI on the basis of professional and site knowledge and a decision is made on the correction or preservation of the data falling outside the pair of limit values.

Part of the results obtained on the basis of this above analysis of the compliance with limit value ranges will be subject to further and stricter testing. There are certain relationships between various water quality constituents. If the measured data do not comply with these relationships then one of the measured values must be faulty. Examples of such relationships are as follows:

| $\mathrm{pH}_{\text {laboratory }}-\mathrm{pH}_{\text {site }}$ | $\leq 0.5$ |
| :---: | :---: |
| $\mathrm{M}_{\text {alkalinity }}$ | < $\mathrm{P}_{\text {alkalinity }}$ |
| $\mathrm{COD}_{\text {d, original }}$ | $>\mathrm{COD}_{\mathrm{d}, \text { settled }}$ |
| $\mathrm{COD}_{\mathrm{p} \text {, original }}$ | $>\mathrm{COD}_{\mathrm{p} \text {, settled }}$ |
| $\mathrm{COD}_{\mathrm{p} \text {, original }}$ | $>\mathrm{COD}_{\mathrm{k}, \text { original }}$ |
| $\mathrm{COD}_{\mathrm{p}, \text { setled }}$ | $>\mathrm{COD}_{\mathrm{k} \text {, settled }}$ |
| Total N | > Mineral N |
| Total P | $>\mathrm{PO}_{4}-\mathrm{P}$ |
| Total cation equivalent | $\approx$ Total anion equivalent |
| Total hardness | > Carbonate hardness |
| Total dissolved solids | $\approx 0.7 \mathrm{x}$ conductivity |
| Total metals | > total dissolved metals |

All those data, which proved to be correct in both formal and professional testing, will be entered into the water quality data base.

## Water quantity data of the data base

At the time of taking water samples a reading of the nearest water level gauge is made. Discharge data are obtained from the so called Q-H rating curves (the relationship between water stage and flow). Unfortunately this Q value is the weakest element of the chain. There is more than one reason for this. The first is the shortcoming of information transfer between hydrologists and water quality experts. Another reason is the instability of the Q-H curves, due to the changes of the channel bed.

Systematic correction of discharge data, in close cooperation with hydrologists, started in 1994 and is being currently made. In this correction work KGI proceeds from the large water courses towards smaller ones and backward in time. This means, for example, that the water flow data of the river Danube can be considered reliable for the past 15-20 years and absurdly high and low flow data had been filtered out from earlier records as well. The case is similar for the medium size water courses but the corrected period is shorter than that of the river Danube. For the small water courses only the filtering of absurdly extreme discharge data can/could be made and this process is still under way [16.].

## Impact of changes in the mean time

Regarding the length of the time series of $150+91=241$ stations mentioned in section 4.1 .2 . the following statements can be made:
$>$ The number of stations with uninterrupted records (in the periods 1968-1997 and 19691997) is 126 , the majority of whose operate since 1968.
$>$ The number of stations operating with smaller or larger interruptions since 1968 or 1969 is 22.
$>$ At the rest of the stations observation has started either in 1975 (Lake Balaton), 1985 and 1994, at the onset of new standards.

The type and number of parameters have not changed much between 1968 and 1994. Smaller changes were as follows:
$>$ Between 1968 and 1977 there was much uncertainty regarding the question whether $\mathrm{COD}_{\mathrm{d}}$ and $\mathrm{COD}_{\mathrm{p}}$ should be determined from settled or filtered samples. Since 1977 both parameters have been determined from the original sample.
$>$ There was another question regarding $\mathrm{COD}_{\mathrm{d}}$ and $\mathrm{COD}_{\mathrm{p}}$ (mostly among foreign experts), namely; why to measure both? The answer is simple. Our upstream neighbors measure(d) almost exclusively $\mathrm{COD}_{\mathrm{p}}$, thus we could not disregard this parameter. However, Hungarian standards request the measurement of $\mathrm{COD}_{\mathrm{d}}$ for characterizing wastewater discharges. Thus in order to remain able to compare emission and immission values we have to measure both.
$>$ The scope of water quality parameters and indices has been changed in 1994. New components have also been included. This referred to various groups of components: components of the plant nutrient cycle (Total N and Total P ); inorganic micropollutants (aluminium, arsenic, boron, cyanide, zinc, mercury, cadmium, chromium, nickel, lead and copper), organic micro pollutants (Chloroform, carbontetrachloride, trichlorethylene, tetrachlor-ethylene, lindane, malation, 2-4D, MCPA, atrazin adn PCB); hydrobiological parameters (Chlorophyll-a, Pheophytin, total algae count,, zooplankton, algae biomass); microbiological indices (coliform count, faecal coliform, faecal streptococcus, clostridium, total telepszám at $22{ }^{\circ} \mathrm{C}$, and at $37{ }^{\circ} \mathrm{C}$ ); radioactivity indices (total beta activity, cesium-137). Among the above mentioned parameters total N, total P, heavy metals (with the exception of arsenic, boron, and cyanide), chlorophyll-a, coliform count and total beta activity are the most frequently measured ones [16.].

## Changes in analytical methods

Before 1968 the methods of laboratory analysis were characterized with high heterogeneity. After 1968, however, the methods of the American Standard became known also in Hungary and they were utilized when establishing the unified analytical methods of the COMECON countries.

Data of the first years after 1968 should be, however, still handled with care, due to reasons other than the heterogeneity of analytical methods. The restricted reliability is due to the fact that in 1956 the development of the laboratories of the district water authorities started from nothing and it took considerable time until they recruited appropriately qualified staff and had their work accepted in the water authority where the bulk of the activities was related to flood control and excess water drainage. The gradually upgraded instruments and equipment resulted, eventually, in increased analytical reliability.

Substantial change in the analytical methods was made in respect to orthophosphate phosphorus only, in the early 1980-ies. The exact date can not be given since it was "laboratory-specific", that is occurred at different times at the various laboratories, depending of the purchase of the respective instruments. In respect to mineral oil (UV) one cannot state that the database is homogenous in the whole country.

## Comparable time series

As a consequence of the conditions discussed above, the length of water quality records, which can be considered homogenous, is more than 25 years. Orthophosphate and mineral oil are the exceptions among the traditional components. In respect to the new water quality indices, which were included in the analysis in 1994, the accuracy of organic micropollutant data remains questionable due to the low frequency of the analysis.

## Suspended sediment and sediment load

The analyses of water samples always include (even before 1968) the total suspended solids (TSS). The analytical method basically differs from the one used in hydrology for the determination of suspended sediment and thus the two types of data can not be compared. Bed-load is not determined from the water samples.

### 4.4. River Channel Characteristics

Hungary has outstandingly long tradition in hydrography, river regulation and water management. The Hydrographic Service was established in 1886. As a consequence of this long tradition there are long practical experience, wide-range knowledge and large amount of data and publications on the characteristics of the water resources in the country. The first volume of the Hydrographic Yearbook was issued in 1887. This Yearbook is published every year by the Institute of Hydrology of the Water Resources Research Center VITUKI Plc., commissioned for this task by the Ministry for Transport, Communication and Water Management (KHVM) in Budapest.

The Hydrographic Yearbook contains a large variety of basic data for research, planning and control purposes on the characteristics of the different river sections and flow conditions, as well as the basic data of the observation wells. The latest Hydrographic Yearbook 1996 [22.] was published in 1997 and as a novelty a CD-ROM is attached, which contains a large amount of hydrological and water quality detail will be soon available also in this form too. To introduce the available data sets from this Yearbook, an example is given concerning the important Danube River section at Nagymaros (rkm 1694.6) as follows:

- Hydrometeorological characteristics,
- Basic data of the observation station
- (registration number, elevation, coordinates, catchment area, etc.)
- Daily, monthly and annual characteristic water level (stage) values,
- Water level curve of the year 1996,
- Stage duration values (written stage duration curve) for 1996,
- Daily, monthly, annual and multi-annual characteristic water flow (discharge) values,
- Hydrographs (water flow curve) of the year 1996,
- Flow-duration values (written flow duration curve) for 1996,
- Specific annual runoff in $1 / \mathrm{s} / \mathrm{km} 2$,
- Data on bed load and suspended load conditions,
- River bed profile (cross-section profile),
- List of flow measurement stations.

Similar data are available from the Yearbook also for other important river sections in Hungary.

Information on the channel profiles and gradients of the main rivers in Hungary are presented in the Hydrographic Atlas Series (HAS), which are public proceedings and available for any professionals for utilization. Detailed information for example about the river Danube is included in the three volumes of HAS No. 11. [23.]. These volumes contain a general description of the hydrography and geomorphology of the river's direct catchment as well as information of the changes of river bed conditions. Moreover the wide range of information cover also:

- List of bench marks along the river;
- Detailed map of the Hungarian section of the river (1:10000) controlled by airphotogrammetry, showing the embankments, river regulation structures, flood protection dikes, and sites of stages, cross-sections, bridges, confluence of tributaries;
- Longitudinal section (gradients) of Danube (1:100, 1:200 000) illustrating the shore-lines, dikes, bottom of river bed, sites of stages, bridges, cross-sections, confluence of tributaries;
- Registrated cross-sections (1:250, 1:5000);
- Valley cross-sections (1:500, 1:10 000);
- Bridge cross-sections (1:500, 1:2 500);
- Grain-size distribution curves of the river bed material in the registrated cross-sections.

Similar information are available about river Tisza in six volumes of HAS No. 22. [24.]. There are altogether 26 items of the Hydrological Atlas Series (HAS) covering all the important rivers in Hungary. These items are publicly available in technical, or scientific Public Libraries for those who are interested in. The best source of the HAS items is the Scientific Library of the VITUKI Plc. in Budapest.
The present National Reviews do not contain those data, which are publicly available in printed Yearbooks, Atlases and in other widely accessible information sources.

### 4.5. Floodplains/Wetlands

The establishments of the flood and excess water control are discussed in this chapter and also the floodplains/wetlands from point of view of nature conservation and water pollution problems.

### 4.5.1. Flood and Excess Water Control

The regulation of the water environment received an impetus in Hungary in the late 18th century, according to the requirements of the society. The construction of the system of flood protection embankments and the drainage of wetlands had been finished during the following 100-year period up to the end of the 19-th century. However the improvement of flood protection structures according to the rise in the value of the protected area and the development of the system of drainage canals and pumping stations have continued until now. One third of the total territory of the country lies under the level of floods and the system of drainage canals and pumping stations enables the normal functioning and protection of economic activities.

The areas of flood control and land drainage in Hungary are illustrated in Figure 4.10. Almost onequarter of the country was exposed to extended or periodic inundation. The Figure shows both the flood plains and the lands above the flood level. Once the latter had been fully exploited economically early in the past century, society was compelled to encroach upon the flood plains and to confine the areas dominated by water i.e. introduce flood control. This vast transformation though completed essentially during the past century - is still being perfected and expanded. As a result, flood control has been introduced over $25,000 \mathrm{~km}^{2}$ of the ancient flood plains, and flooding now is confined to the $1,500 \mathrm{~km}^{2}$ area between the flood levees. The main-line levees of 4.200 km total length, provide flood safety for about 45 per cent of the territory of the country inhabited by almost one half of the population. The flood waves travel down the rivers with peak stages considerably - on occasion several meters - higher than under the original conditions [25].

A corollary of the construction of the levees has been the need to provide artificial drainage to vast areas at times of high stages. The protected flood plains have accordingly been subdivided into 83 polders. To illustrate the drainage capacity it should be noted that the total length of drainage canals surpasses 40000 km , while about 450 pumping stations are capable of lifting a discharge of $840 \mathrm{~m}^{3} / \mathrm{s}$ across the levees. The overall discharge per unit area thus reaches $28.5 \mathrm{1} / \mathrm{s} / \mathrm{km}^{2}$.

### 4.5.2. Nature Conservation in the Floodplain/Wetland Areas

Aquatic/wetland ecosystems used to be and are still endangered. At the same time it has to be mentioned that Hungary was very rich in perennially and temporarily inundated areas, until the beginning of large-scale river-regulation works and land-reclamation activities (which actually begun already during the era of the Roman empire's presence in the western parts of the country, called at that times: Pannonia). In spite of very extended human impact on aquatic/wetland sites huge areas survived and there exists a great number of former wetland areas which are not yet beyond irreversible status, which can be still reconstructed. Hungary has quite a reputation in very effective revitalization-renaturalization of former wetlands. Just recently an extended work is done for the "complete" inventory of existing wetland areas and sites which can be still reconstructed. The work is based on the application of remote-sensing methods for such purposes and will lead to a categorization of such areas, plus the edition of an atlas on wetlands in Hungary. Kind of a manual will be available for NGOs in order to promote the participation of the public in similar activities.

The protected areas in Hungary are grouped into the following basic types:
> freshwater aquatic ecosystems,
> wetlands/floodplain ecosystems, and
> terrestrial ecosystems.
National Parks (NP), Landscape Protection Areas (LPA) and Nature Reserves (NR) were established for the protection of the most important ecosystems mentioned above and their location are illustrated in Figure 4.11.

The most important Hungarian wetlands (Ramsar sites) of international importance [26.] are listed in Table 4.7., and their location is illustrated in Figure 4.12.

Table 4.7. Hungarian wetlands of international importance

| No. | Name of site | Area <br> Code <br> No. | Year of <br> Regist- <br> ration | Size <br> In <br> Hectares |

| 19 | Biharugra Fish-ponds | 12 | 1997 | 2791 |  |  |
| Total area of important wetlands: |  |  |  |  |  | $\mathbf{1 4 9} \mathbf{8 4 1}$ |

It is important to note, that at present data are not available at all on the hydraulic loading of the wetland areas. Further studies are needed in this respect to have scientifically based knowledge for maintaining the best water management of these areas. Some of the most important wetlands are briefly discussed below from point of view of nature conservation aspects:
Fertő - Hanság NP- the lake is shared by Austria and Hungary. Area and depth are strongly depending on precipitation partly directly, partly by the floods of Danube. The lake is without natural outlet, thus having an alkaline character. The lake, the Hanság, the Szigetköz (and the Csallóköz) are forming a unique hydrological, hydrogeological, geomorphological and ecological unit. An almost complete series of freshwater and wetland habitat classes can be found in the area. Significant habitat types are the open-surface water bodies for migratory birds, the huge reed-beds for nesting of mixed heron colonies, the tall wet meadows and grasslands for geese and ducks, the short temporarily wet grasslands for different waterfowl and the barren soil surface- short grassland habitats, which preserve specific nesting bird species. The wet meadows are abundant in orchids. The Hanság lies east of Lake Fertô, a perfect plain hardly influenced by human activity (drainage, agriculture, extraction of peat). Communities: alder - fern bogs, hard wooded gallery forests, wet meadows rich in orchids, peat bogs, extended grasslands with a good population of Great Bustard.

Gemenc LPA - Hungary's largest wooded floodplain partly preserving the ancient status characteristic before river regulations. It is dissected by abandoned side branches and holds many swamps and other wetlands. The protected area is located between the flood protection dikes. The quality of water is good. The area has lush undergrowth and is rich in game. The woods are mainly oak - ash - elm. Snowdrop, Blue Star, Lily of the Valley are characteristic plants here and the clearings covered by native grasslands. Nesting birds are White-tailed Eagle, Saker, Lesser Spotted Eagle, Black Woodpecker. Large colonies of bats are unique feature of the area.

Kis - Balaton LPA - the area used to be part of the Lake Balaton basin, until it was drained in the last century. In the 1980's the first phase of its reconstruction began. Thus part of the former area became wetland again. It functions as natural filter, sediment and nutrient trap for the river Zala before entering Balaton. It is a waterfowl nesting and migrating area of international importance. The number of species is about a hundred. It is a Ramsar site.

Hortobágy NP -the largest NP, a continuous area which used to be an alkaline lowland area built up and regularly flooded by Tisza. From the beginning of the $19^{\text {th }}$ century river regulation works significantly altered the water regime of the area. Today it contains a mosaic of open water surfaces, bare alkaline patches, alkaline swamps and marshes, meadows, loess grasslands and alkaline short grasslands, small patches of native oak forests and a series of fishponds. Its mosaic-like character comes from geological and edaphic differences and differences in elevation.

In the region from the European bird fauna more than 400 species were observed. The flora is also very rich according to the various habitat types listed above. An important genetic pool is preserved in the Park from ancient domestic animals. Their role is vital in maintaining the ecological balance of the "puszta" by grazing. Wetland reconstructions carried out in the area are important in a context of continental examples as well, and the water regime is adjusted to the movements and activities of birds.

## Water quality problems of wetlands in general

Water quality problems related to wetlands might have several reasons. The two main types of these reasons are: the problems caused by natural processes, and the man-made (antropogenous) impacts. Very often it is not easy to separate the two types, because minor (hardly detectable) human impacts might trigger natural processes of much bigger effect. Very important regulating cycles of a clean/clear river course (a water body in general) are the sequence of: inorganic matter -- algae -- small crustaceans -- fish -- organic matter -- bacteria -- inorganic matter. In case this cycle is disturbed (e.g. by contamination) stability of it might be destroyed by fast multiplying bacteria and their high oxygen demand.

Water quality and - quantity issues can be hardly separated - changes in quantity result almost always in alteration of quality. Algal blooms, might be caused by long lasting high water temperature and high amount of nutrients; mass fish killing by viruses, bacteria, parasites as well. High concentration of suspended load can block penetration of light. But in the background there ought to be human impact (in the form of contamination, e.g. by toxic waste, thermal influx etc.), which is lowering the power of resistance of fish - flora and fauna in general.

## Fertõ-Hanság National Park (NP) Directorate

Lake Fertõ is a steppe lake appearing in document since the Roman times, now it is shared by Austria and Hungary. The water resource of the lake originates from precipitation and surface watercourses. The water is shallow and has a salt-content (since it had originally no natural outlet and thus the level of it was mainly regulated by evaporation; and by an artificial canal. It is a 'Man and Biosphere' Reserve since 1979. An integral part of the lake is the Hanság swamp, which was fed (via surface and subsurface water) by the floods of Danube. The Szigetköz, the Hanság and the Lake Fertõ have been a common and singular hydrographical unit, until the introduction of human impact ("amelioration" of the Hanság, peat digging and the construction of the Gabčikovo Impoundment and hydropower plant). The establishment of wastewater treatment plants around the lake improved the water quality, and the risk of municipal nutrient load is decreased. Due to the changes in agricultural production, the non-point source pollution load is also much less than before.

## Balaton Upland NP Directorate

Little (Kis) Balaton swamp and the Lake Balaton itself used to be one single unit including the inundated valleys ('berek's) adjacent to the southern side of the Lake. Kis Balaton was drained, ameliorated in former times and the bereks were partly drained and partly contaminated by agriculture (mainly stock breeding). Kis Balaton is recently reconstructed, thus acting again as a trap of suspended load which has partly silted-up the W-ern basin of the Lake during the years when the Zala River was running fast and directly between dikes to the recipient. Today the water of the river is again retained in the Kis Balaton Basin, but the original/natural water-household balance will be hardly achieved very soon, if ever. Until this situation, the existing problem caused by the more or less stagnant water will be there too: partly because the water becomes too warm, the formally settled sediment and its contaminants can be stirred-up and aquatic vegetation (reed) is not able to eliminate harmful matters.

## Duna-Ipoly NP Directorate

Lake Velence. According to historical data it became dry in about every hundred years. It is shallow and was originally supplied by surface water courses fed partly by karstic springs. The water of the two main brooks was for irrigation purposes held behind barrages and the karstic springs became dry as a consequence of dewatering activities of (bauxite and coal) mines. A dry period lasting for more than a decade brought then the lake into a very labile situation. The lake and the adjacent Dinnyési Fertõ (swamp) had to be supplied by water artificially. The water was pumped from Danube and later from a mine, which is an expensive issue. The artificially supplied water had a rather unfavorable quality and caused problems as well (the karstic water from the mines was contaminated). Recently the original/natural water household of the lake becomes balanced again and so the quality problems will be eliminated too.
Tata Great Lake (Tatai Öregtó). It is an artificial lake built by the Romans. The lake is fed by the Általér Creek and used to be fed by lukewarm karstic springs to be found on the bottom of the lake. The Általér Creek was heavily polluted by pollutants from mining, and industrial activities, not treated wastewater effluents, agriculture pollution load and suspended load (erosion of cultivated land!) as well. The karstic springs became dry as a result of the mining activities. Life in the lake was almost lost and the lake as a recreational area and an element of the landscape destroyed. Reconstruction works begun years ago and brought good results.

## Hortobágy NP Directorate

Kisköre Impoundment/Reservoir. The dam was built originally for several purposes (power plant, irrigation, navigation) and was never filled up to its full capacity, because of maleffect on agriculture. At the beginning the quality of the water was not suitable for a period of time, partly because of the trees in the lake, which were not removed from it in advance. Today it is a famous recreational area, but because of the lack of proper infrastructure, investments are still necessary in order to avoid problems.

Hortobágy. In the NP recently (partly by foreign aid) wetland areas were reconstructed and thus the former status of the "Puszta" is reappearing, at least in relatively small parts. Prior to the river regulation works of the last century, large areas of the Hortobágy were regularly inundated by the floods (usually twice a year) of the river Tisza. The "original" water quality of the perennially and temporarily inundated areas was obviously determined by these floods. After the river regulation (and amelioration) activities the river Tisza had (except for catastrophic events) to flow within the dikes and thus the very broad floodplain became dry and the depression were only filled up by water fed by precipitation and some minor, almost temporary water courses. The former river branches (having been separated from the river itself) became oxbow lakes and were sooner or later silted up. The reconstruction and revitalization of these is also an integral part of the activities carried out by the Directorate. Here again the main aim is to provide water in the necessary quantity and quality.
Figure 4.10. Flood plains and main levees in Hungary

Figure 4.11. Areas for the protection of important ecosystems

Figure 4.13. River impoundments and reservoirs

### 4.6. Dams and Reservoirs

The most important establishments of hydropower generation (impoundments) and reservoirs to serve different water usages are discussed under this chapter. The "Part A: Social and Economic Analysis" of the National Review briefly discussed the establishments of hydropower generation in Hungary in chapter 5.1.4. and some of the main characteristics are summarized in Table 5.1.4. There are only two among the listed hydropower stations and their impoundments which have national importance, located at Tiszalök and Kisköre on the river Tisza. Additional information on the most important characteristics of these impoundments and hydropower stations are given below.

### 4.6.1. Hydropower Stations and Their Multi-purpose Impoundments

The Tiszalök (Tisza I.) Impoundment was put into operation in 1954. The system consists of the dam of the impoundment with three weirs at the rkm 524.2 section of the river Tisza, the hydropower station with three Kaplan turbines of $100 \mathrm{~m} 3 / \mathrm{s}$ flow-capacity and the ship-lock to maintain navigation. The presently available hydropower productivity is 7.2 MW . The average headwater is plus five meters (maximum 7.2 meters).
The main task of the Tiszalök impoundment system is to provide water for agricultural use (irrigation) for the northern part of the lowlands (Alföld) in the Tisza valley, where an area of 120,000 ha was planned for irrigated cultivation (Tiszalök irrigation system). From the impoundment a water flow of $60 \mathrm{~m}^{3} / \mathrm{s}$ can be delivered to the agricultural units through the Eastern Main Canal and the Western Main Canal. Because of the good quality of water the Eastern Main Canal is also utilized for drinking water purposes. Due to the substantial cost-factors of the irrigation and the relatively low financial power of the agricultural units in this area, the utilization of irrigation possibilities is rather low.

The Kisköre (Tisza II.) Impoundment system consists of the dam at the rkm 403.5 section of the River Tisza, the hydropower station with pipe-turbines and the ship-lock to maintain navigation. The presently available hydropower productivity is 15.5 MW .
The main objective of the establishment of the Kisköre impoundment system was practically the same as that of the Tiszalök system, to store and provide water for the agricultural uses, first of all for irrigation purposes. The Kisköre reservoir has a storage capacity of 260 million $\mathrm{m}^{3}$ during the low flow period of the river Tisza. The impoundment system is able to meet the irrigation water demand of a cultivated area of approximately 400000 ha . The water for this purpose is distributed by two main canal networks, on the left from the reservoir through the Jászság Main Canal, and on the right the Kiskúnság Main Canal.

The Kisköre impoundment system naturally serves other purposes as well, for example it has a significant flood protection role by equalizing peak flow conditions in the river, and during the recent years it developed into a very popular recreation area for water sports and tourism.
The following small size hydropower plants in operation on smaller rivers have only local importance from point of view of energy production and water management:

$$
\begin{array}{lll}
\text { Ikervár: } & \text { River Rába at rkm 100.56, } & \text { capacity } 1.5 \mathrm{MW} \\
\text { Kesznyéten: } & \begin{array}{l}
\text { River Hernád at } \mathrm{rkm} 13.56,
\end{array} & \begin{array}{l}
\text { capacity } 2.8 \mathrm{MW}
\end{array} \\
\text { Felsódobsza: } & \begin{array}{l}
\text { River Hernád at rkm } 54.35, \\
\text { capacity } 0.2 \mathrm{MW}
\end{array} \\
\text { Gibárt: } & \text { River Hernád at rkm } 65.9, & \text { capacity } 0.4 \mathrm{MW} .
\end{array}
$$

The Kvassay-Weir with ship-lock and hydropower station is located in Budapest at the upper mouth of the Ráckeve-Soroksár Danube Branch. It was constructed first of all to protect the Danube Branch from flood effects and also to provide water level control and navigation possibilities. The water level management ensures the operation of water intakes for industrial water supply and irrigation. The hydropower station has 1.6 MW capacity for energy production, the average head is 4.6 m . The Tassi-Weir is located at the lower end of the Ráckeve-Soroksár Danube Branch. During the high flood event in early spring of the year 1956 the building of the weir broke down because of subsidence.
The Nick-Barrage was built on the river Rába at rkm 65.5 with the purpose to provide planned water quantity for the creek Little Rába for water supply purposes.
The Békésszentandrás-Barrage is located on the river Kettős Körös at rkm 48.0. It was built in the forties to provide irrigation water for the agricultural units in the Körös valley and to assist the navigation in that area. There is a weir with double tables, headwater is about 5 meters in average. The barrage system is capable to provide irrigation water for an area of 20000 ha .
The location of the above discussed impoundments and barrages are illustrated in Figure 4.13.

### 4.6.2. Reservoirs

The existing reservoirs in Hungary were established generally in the catchment areas of relatively small river courses and they serve different purposes. Most of the reservoirs were built for agricultural utilization (mainly for irrigation purposes) and also for industrial and public water supply purposes. Some of them serve low flow augmentation or/and recreation. Especially on the lowlands of the Tisza valley there are several big excess water reservoir, which are mostly filled up only during the very wet periods to avoid the inundation of the cultivated areas. The main characteristics of the most important reservoirs (above four million m3 storage capacity, but without the excess water reservoirs) are summarized in Table 4.8.

The location of the important impoundments and barrages discussed are illustrated in Figure 4.12. , in which the numbering refers to the row-numbers of the above Table.

Technical details on some of the reservoirs being important from point of view of drinking and industrial water supply is provided as follows.
The Komra-Valley Reservoir is located on the Komra Creek at rkm 1.094 with a storage capacity of 4.5 million $\mathrm{m}^{3}$. The reservoir is filled up from River Ipoly (primary tributary of Danube) by pumping up the water into the reservoir. For this purpose a barrage was built at the river section of rkm 125.2. The elevated water goes through a six-step aeration cascade before entering the reservoir. The main task of the reservoir to supply raw water for drinking water purposes for the regional Waterworks of the ENRV (Regional Waterworks of North Nógrád County). The effective water intake for this purpose is $24200 \mathrm{~m}^{3} /$ day .

Table 4.8. Characteristics of important impoundments and reservoirs

| No. | Reservoir | River, or <br> Water Course | Area <br> Code <br> No. | Storage <br> Capacity <br> Million m3 | Main use |
| :---: | :--- | :--- | ---: | ---: | :--- |
| $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ |
| 1. | Komra-valley | Komra Creek | 2 | 4.5 | Drinking water |

| 11. | Markaz | Nyiget Creek | 8 | 8.4 | Ind.water+irrigation |
| 12. | Tata Great Lake | Átalér Creek | 9 | 5.2 | Recreation |
| 13. | Kisköre Barrage | Tisza | 10 | 260 | Irrigation+recr. |
| 14. | Békés Barrage | Kettős Körös | 12 | 6.7 | Irr.+water suppl. |
| 15. | Békéssztandr. Barr. | Hármas Körös | 12 | 20.0 | Irr.+water suppl. |
| 16. | Bökény Barrage | Hármas Körös | 12 | 12.0 | Irrigation |

The Lázbérc Reservoir is located on the Bán Creek (secondary tributary of River Tisza), near the village Bánhorváti at rkm 10.3 serving the drinking water supply system of the Borsod Industrial Region. The catchment area of the reservoir is $260 \mathrm{~km}^{2}$ and the storage capacity is 5.9 million $\mathrm{m}^{3}$. The reservoir belongs to the Borsod Regional Waterworks and provides $20000 \mathrm{~m}^{3} / \mathrm{day}$ water for public supply purposes.

The Rakaca Reservoir was built on the Rakaca Creek (secondary tributary of River Sajó) in the neighborhood of the village Szalonna and its dam is located at rkm 20.3 of the creek. The storage capacity of the reservoir is about 5.5 million $\mathrm{m}^{3}$. The reservoir belongs also to the Borsod Regional Waterworks and works for low flow augmentation. It provides $0.7 \mathrm{~m}^{3} / \mathrm{sec}$ flow during low flow periods for downstream water users along the Bódva Creek, mainly as raw water for drinking water production purposes.
The Mátra-area Regional Waterworks has two small-size reservoirs to provide raw water for public drinking water supply purposes. The Köszörû́-Valley Reservoir is located on the Köszörű Creek with a storage capacity of about 1 million $\mathrm{m}^{3}$. The raw water supply in average is $2,000 \mathrm{~m}^{3} / \mathrm{day}$. The Csórrét Reservoir uses the water resource of the Gyöngyös Creek and has an effective capacity of about 1 million $\mathrm{m}^{3}$. The quantity of the raw water provided is $3,000 \mathrm{~m}^{3} / \mathrm{day}$ also for public supply purposes.

## Sediment trapping effect of reservoirs

There are only two large impoundments affecting the main rivers in Hungary, which could represent significant sediment trapping effects to be considered in regional studies: in case of Danube the Gabčikovo Impoundment (Čuňovo Reservoir) and in case of the river Tisza the Kisköre Reservoir. The sediment trapping effects of other reservoirs situated on the small tributaries of the river system in Hungary (listed in Table 4.8.) have no significance from point of view of transboundary analysis in the Danube River basin.

Danube: impacts of the Čuňovo Reservoir. The Water Quality Protection Working Group of the Slovak-Hungarian Transboundary Water Commission carried out detailed investigations on the tendency and dynamics of water quality changes observed during the period of 1989-1995 concerning the common stretch of Danube and its tributaries [27.] The following findings were published in their summary report on the observed changes of the suspended solids (TSS) content of the river water measured upstream and downstream from the reservoir:
"The maximum concentrations of suspended solids have changed by several
$100 \mathrm{mg} / / \mathrm{during}$ the past six years. More uniform variation characterizes the
90 percentile values. In the section of Medved'ov/Vámosszabadi the suspended
solids content has substantially decreased due to the effect of sedimentation in the
reservoir of Čuňovo. The remarkable differences between the sediment
concentrations of the river reach of Bratislava and Medved'ov/Vámosszabadi can
clearly be demonstrated by the measured data of the period October 1992 -
December 1995."
The statistics of the measured TSS values (in $\mathrm{mg} / \mathrm{l}$ ) of the corresponding period were:

| Station | Min. | Max. | Mean(M) | Median | St.dev. | St.dev/M | C90\% Quality Class |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Bratislava | 6 | 227 | 33 | 26 | 36 | 1.09 | 58 | IV. |
| Medved'ov/Vámosszab. | 6 | 319 | 29 | 20 | 39 | 1.35 | 44 | III. |

Data given by the detailed report of the evaluation of quality monitoring data [28.] however reflects some uncertainty on the suspended sediment retention impact of the reservoir, thus further detailed studies are needed in this respect.

River Tisza: impacts of the Kisköre Impoundment. There are no regular multi-point measurements on the suspended load in the upstream and downstream sections of the reservoir, the local laboratory fortnightly takes only one-point samples. These data can not provide full picture on suspended load conditions. During the higher storage level ( 720 cm ) in summertime the measured concentrations are usually not higher than $10 \mathrm{mg} / \mathrm{l}$. In wintertime however, having the lower storage level ( 520 cm ) during flood periods the measured suspended load density at the upstream section of the reservoir reached even the value of $1000 \mathrm{mg} / \mathrm{l}$ too. The rate of the silting up of sediment is very small in the large flat areas of the bottom of the reservoir, but it is much higher in the ox-bow bends. Data on sediment retention impact of the reservoir is not available at present.

### 4.7. Major Water Transfers

There are only few major water transfers (intakes) from the Danube and Tisza Rivers, which are in the magnitude of the ten percentile monthly low flow. In case of Danube there are two power station cooling water intakes, which are discharged back with higher temperature with certain losses. In the river Tisza basin there are water intakes for agricultural utilization (irrigation) transferred by the Main Channels towards the irrigation systems. The most important major water intakes are listed in Table 4.9.

Table 4.9. Major water transfers from the Danube and Tisza Rivers

| No | Site of water intake | River <br>  <br> Rkm | Area <br> Code <br> No. | Water intake |  | River mean flow |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | LicenSed | Actual |  |
|  |  |  |  | m3/s |  |  |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| 1. | Százhalombatta Power St. | Danube <br> Rkm 1600.2 | 4. | 25 | 24 | 1080 |
| 2. | Paks, Nuclear Power St. | Danube <br> Rkm 1500.3 | 4. | 110 | 110 | 1140 |
| 3. | Tiszalök, Eastern Main Canal | Tisza <br> Rkm 524.2 | 9. | 60 | 50 | (69) |
| 4. | Tiszafüred, Main Canal | Tisza $\text { Rkm } 404.0$ | 10. | 6 | 3 | (52) |
| 5. | Jászkunság Main Canal | Tisza <br> Rkm 403.5 | 10. | 48 | 16 | (52) |
| 6. | Nagykunság Main Canal | Tisza <br> Rkm 243.6 | 11. | 82 | 50 | 101 |

The values in brackets in the column No. 7 indicate that the water intake for irrigation is taken from an impoundment, independently from the actual value of monthly low flow conditions of the river. The sites of these intakes are illustrated in Figure 4.13.

### 4.8. Preferred Sampling Stations

For the purpose of transboundary diagnostic analysis and basin-wide water quality simulation studies data sets and sampling sites of the existing water quality monitoring stations were analyzed. This analysis took also consideration the results of the recently completed Phare Project EU/AR/303/91 "Development of a Danube Alarm Model" from point of view of river sections taking into account for modeling purposes [29.]. As a result of this analysis the preferred water quality monitoring stations advised for further basin-wide studies are listed in Table 4.10.

Table 4.10. Preferred water quality monitoring stations for basin-wide studies

| No. | River | Monitoring site | River km | TNMN | Bucharest <br> Declaration |
| :---: | :--- | :--- | ---: | :---: | :---: |
| $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{7}$ |
| 1. | Duna | Medve | 1806.0 | Yes | Yes |
| 2. | Duna | Szob | 1708.0 | Yes | Yes |
| 3. | Duna | Dunaföldvár | 1560.0 | Yes |  |
| 4. | Duna | Hercegszántó | 1435.0 | Yes | Yes |
| 5. | Rába | Szentgotthárd | 202.6 |  |  |
| 6. | Ipoly | Ipolytarnóc | 179.0 |  |  |
| 7. | Sió | Szekszárd-Palánk | 13.0 | Yes |  |
| 8. | Dráva | Drávaszabolcs | 68.0 |  |  |
| 9. | Tisza | Tiszabecs | 757.0 |  |  |
| 10. | Tisza | Tiszasziget | 162.5 | Yes |  |

| $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{7}$ |
| :---: | :--- | :--- | ---: | ---: | :---: |
| 11. | Sajó | Sajópüspöki | 123.5 | Yes |  |
| 12. | Bódva | Hidvégardó | 63.7 |  |  |
| 13. | Hernád | Tornyosnémeti | 102.0 |  |  |
| 14. | Bodrog | Felsőberecki | 46.0 |  |  |
| 15. | Szamos | Csenger | 45.4 |  |  |
| 16. | Kraszna | Mérk/Ágerdőmajor | 42.2 |  |  |
| 17. | Berettyó | Pocsaj | 71.5 |  |  |
| 18. | Maros | Nagylak/Makó | 50.6 |  |  |

The list of the above Table contains the most important regular water quality monitoring stations at the border sections of rivers entering the country. The list includes all the stations, which are selected monitoring stations for the Trans-National Monitoring Network of the Environmental Programme for the Danube River basin [30.] and also those stations which participate in the Bucharest Declaration monitoring programme [31.]. The locations of these monitoring sites are illustrated in Figure 4.14.

Several other stations of the routine water quality monitoring network had the role of preferred station during the studies on selecting the municipal and industrial hot spots, discussed in chapter 2. The closest upstream and downstream sampling stations were considered from this respect, and measurement data were compared to assess the impact on the recipient water bodies, as well as the results of the wastewater discharge control investigations of the District Environmental Protection Inspectorates.
Basic water quality data series for the period between the years 1994 and 1997 are provided for the further basin-wide studies consisting 15 of the above listed stations in a separate volume (Volume II) as part of this National Review update, discussed later in chapter 4.11.

### 4.9. Water Discharges

There are no simultaneous flow measurement carried out at the time of the regular and scheduled water quality samplings of the routine monitoring network, which is harmonized between the local Environmental Protection Inspectorates. The problem of getting simultaneous water quantity (river flow/discharge) and quality data was discussed in chapter 4.3. (data consistency, compatibility and transparency) and the methodology of generating flow data for the corresponding sampling action was described. Controlled and reliable flow data for a given date can be get from the Hydrological Data Bank at the Institute for Hydrology in VITUKU Plc. Dissemination of the data is made through the Hydrological Yearbooks (see: chapter 4.4.).
Significant efforts are made on the continuous correction of river discharge data belonging to each water quality data. This activity is carried out with the close cooperation of the experts working in the field of hydrology and water quality and it is still going on. The available multi-annual hydrological observation system and database provide substantial background for this activities. Generally it can be stated that flow data attached to the water quality determinations for the period of 1994-1997 have already been improved and are reliable enough for any further studies.
Simultaneous flow measurements and water quality determinations are carried out only during special case-studies and research projects, like environmental impact assessment studies on existing, or planned major emissions, etc.

### 4.10. Sediment Discharges

## Hydrological data on sediment movements

The Hydrological Yearbook 1996 [22.] contains information on the frequency of measurements and data on bed load (bed sediment) conditions of the river system in Hungary. In case of Danube there are 30 years of measurement data on bed loads for six characteristic river sections (Medve, Dunaalmás, Nagymaros, Budapest, Dunaújváros and Mohács) and for the river Tisza there are three measurement sections used for this purpose (Tivadar, Szolnok and Szeged). Altogether there are 23 river sections where regular bed load measurements are carried out. Results consist of the concentration $\left(\mathrm{g} / \mathrm{m}^{3}\right)$, specific load ( $\mathrm{kg} / \mathrm{s}$ ) and total annual amount ( $\mathrm{m}^{3} / \mathrm{year}$ ) of the bed load in the river. Similar data series are available for the suspended load in the rivers, which can not be compared to the TSS (Total Suspended Solids) measured during the water quality monitoring activities, because of different sampling and determination technique. The latest issue of the Hydrological Yearbook (including a CD-ROM with detailed data, completed in 1998) was published by the Institute of Hydrology of VITUKI Plc. in 1997 in Budapest.

The present National Reviews do not contain above publicly available data, disseminated in printed Yearbook as widely accessible information source.

## Water quality data on bottom sediment

Regular quality determinations of the bottom sediment of rivers are not included in the routine water quality monitoring system running at present in the country. However several case studies investigated the quality conditions of bottom sediments in different sections of the river system in Hungary.
Figure 4.14. Border monitoring stations and preferred sampling stations

Basin-wide study on the quality of the bottom sediment of Danube was carried out in 1993 organized by the Equipe Cousteau and VITUKI Plc. This expedition collected on-site samples at 50 locations from the source of Danube to its delta:
> Sediment samples for analysis of organic and inorganic pollutants,
> Mussel samples for studying bioconcentration of chemical pollutants in biological indicators,
> Benthos samples for analysis of diversity of benthic organisms which are a qualitative indicators of the stress undergone by an ecosystem exposed to pollution.

This regional study [provided very valuable information and experiences on the polluting hot spots along the river. To illustrate some of the findings of this study, Figure 15. presents three characteristic longitudinal sections of concentration distribution of the pollutants: "coprostanol" (which indicates the effect of untreated municipal wastewater), "total aliphatic hydrocarbon" (indicating oil pollution) and "mercury". The component coprostanol clearly shows the outstanding pollution effect of the untreated wastewater discharge of Budapest on the bottom sediment of the river, and in case of mercury the major polluting impact of the tributary river Vág/Vah on the recipient Danube. The accumulation of oil pollution impact is also significant.
The most recent study on the problems of bottom sediment quality was carried out by a Consortium led by VITUKI Plc, under the Applied Research Programme of the Environmental Programme for the Danube River Basin. The Consortium elaborated the EU/AR/105/91 Phare Project "Quality of Sediments and Biomonitoring" [29.]. The project developed proposal for the introduction of routine investigation programme for the quality determination of bottom sediment of rivers.

### 4.11. Water Quality Data

Basic water quality data series coming from the regular water quality monitoring network between the years 1994 and 1997 are provided for further studies of the Danube River Basin Pollution Reduction Programme concerning the following monitoring stations:

| Danube: | Szob, | rkm 1708.0 |
| :--- | :--- | :--- |
|  | Hercegszántó, | rkm 1435.0 |
| Ipoly: | Ipolytarnóc, | rkm 179.0 |
| Rába: | Szentgotthárd | rkm 202.6 |
| Dráva: | Drávaszabolcs, | rkm 68.0 |

Figure 15. Results of the basin-wide study on the quality of bottom sediments in the river Danube. (Source: Equipe Cousteau 1993.)

## Distribution of Coprostanol in Danube sediments

## Distribution of „total aliphatic hydrocarbons"

 in Danube sediments

Distribution of total Hg in Danube sediments

| Tisza: | Tiszabecs, | rkm 757.0 |
| :--- | :--- | :--- |
|  | Tiszasziget, | rkm 162.5 (left-middle-right bank samplings) |
| Sajó: | Sajópüspöki | rkm 123.5 |
| Bódva: | Hidvégardó, | rkm 63.7 |
| Hernád: | Tornyosnémeti, | rkm 102.0 |
| Bodrog: | Felsőberecki, | rkm 46.0 |
| Szamos: | Csenger, | rkm 45.4 |
| Kraszna: | Mérk/Ágerdőmajor, | rkm 42.2 |
| Berettyó: | Pocsaj, | rkm 71.5 |
| Maros: | Nagylak, | rkm 29.1 |
|  | Makó, | rkm 25.0 |

These monitoring stations are controlling the sections where rivers are entering and leaving the territory of Hungary. Basic water quality data measured at these stations are given in printed form and on diskette in Annex 10 of this report.

To assist the better understanding of the changes of transboundary water quality conditions ten years statistics of the measured values of selected quality components are also provided in printed form in Annex 10. The water quality parameters cover selected items of oxygen household, nutrients, oils, metals, hydrobiological and microbiological parameters. Statistical compounds are minimum, maximum and mean values, standard deviation and probability values of 10,90 and 95 percentiles. The messages of this statistics speak for themselves, however few notes are necessary too.

The ten years statistics clearly show that due to the significant self purification capacity of the big rivers like Danube and Tisza there is no characteristic change in the entering and leaving water quality concerning oxygen household and slight increase can be observed in nutrient compounds. In case of special parameters (oils, some of the metals, and especially microbiological components) however there are moderate deterioration.

Statistics on the water quality parameters of Tisza tributaries Szamos, Kraszna and Maros clearly show the entering high pollution load into the country: for example the 90 percentile probability value of COD, or Coliform belong in each case into the fifth highly polluted quality class. Several components of the group of micropollutants also belong to the IV-V quality class.

## Comments on the database of 1994-1997

The basic description of the database of the period 1994-1997 was given in the chapter dealing with the history of water quality monitoring. This four years period cannot be separately discussed without viewing the development process as a whole. Some additional information from this respect is summarized in the followings.

The monitoring systems of 1984 and 1994 (and the standards behind them MSz-10-172/1-83 and MSz 12749) differ from each other in three aspects:
$>$ The qualification system which came into force from the beginning of 1985 was based on various water uses (biological stability, drinking water supply industrial water supply, irrigation, fisheries and integrated requirements), while that of 1994 is focused at the water as an ecological unit, disregarding water uses. Instead of this latter different groups of components are specified. The difference is only virtual since the integrated qualification system of the former actually includes the quality indices of all water uses and the limit value system is the corresponding range. The latter cannot be used for qualifying according to water uses. In respect to the second the original concept was that as a continuation of MSz 12749 , which was developed by the environmental ministry

KTM, another system will be developed by the ministry for water management (KHVM) focusing solely at qualification according to water uses. This has not yet been done. According to the available information the ministry KTM will again give a contract for the development of a new system.
> In the system of 1985 the basis of the classification is the $80 \%$ duration value (the $80 \%$ percentile), while in that of 1994 the $90 \%$ value (that is a value which is closer to the measured maximum than in the case of the former one). It is to be noted that in case of fewer than 10 samples the determination of these percentiles is not allowed by the rules of statistics. In this case we usually apply the measured maximum, marking this in a footnote.
> The standard of 1994 (Msz 12749) has substantially expanded the scope of the measured parameters. This has already been discussed and presented in Annex 1.

Both systems classify for each of the components. In the first system the quality class was defined on the basis of the worst component. In the second system the classification is made for component groups, also on the basis of the worst component of that group.

Regarding the data base of the period 1994-1997 and the components selected for water quality modeling the following additional remarks can be made [16.] :
$>$ The number of total N data is limited even after 1994. This can be explained by financial and laboratory capacity reasons. Thus only the mineral N defined as the sum of $\mathrm{NH}_{4}-\mathrm{N}$, $\mathrm{NO}_{2}-\mathrm{N}$ and $\mathrm{NO}_{3}-\mathrm{N}$ can be used. Another solution might be the extrapolation using the ratio of total N to mineral N for the calculation of total N , for those cases when this date is lacking. Unfortunately this ratio shows high variation even in the same sampling point.
$>$ For modeling purposes satisfactory number of total P data can be found in the database. If this is not the case, then the above mentioned extrapolation method can be used, but with much higher reliability than in case of total N .
$>$ Regarding the questions related to COD or BOD it is to be noted that $\mathrm{COD}_{\mathrm{d}}$ characterizes industrial pollution, while BOD - the communal dischargers. We have to use both, since there are numerous sources of both types of pollution in Hungary.
> In respect to heavy metals the attention of experts working with these data should be drawn to two special conditions. The first is that the standard MSz 12749 requests the measurement of dissolved forms. The other one is that the instrumentation of the various laboratories highly differs from each other and the measurement accuracy is also different.
> This also holds for organic micropollutants. Another problem is that large number of data (of higher analytical frequency) is available only for mineral oil, phenols and anionactive detergents. Only scattered data are available for the rest.

## 5. Brief Overview of Legal and Institutional Framework for Water Quality Control

The legal and institutional framework for sound environmental and management of water resources and ecosystems is already discussed in Part A chapter 6 of the National Review. Under chapter 6.2. the relevant organizations and responsibilities are presented in details, covering also the area of water pollution control.
Herewith the most important legislative means (laws, ministerial orders, etc.), regulations and standards in the field of pollution control and prevention are briefly listed and summarized as follows:

## 1995. LIII. Law - The general act of environmental protection

The goal of the LIII. Law is to develop harmonic connection between people and the environment, as well as to protect the environmental elements and processes, and to provide the environmental conditions for the sustainable development. The LIII. Law determines:

1. the environmental protection activity of the Government, the Parliament and the State,
2. the National Environmental Program and
3. the tasks of local governments, Fund of Environmental Protection, Management of Environmental Protection, National Council of Environmental Protection, Minister of Environmental Protection and task of development on research and technology as well.

## 1995. LVII. Law - Water Management

It covers the surface and subsurface waters, as well as the hydraulic structures, the activities with waters and the measurements of conditions of water. The LVII. Law regulates:

1. the public activity of water works,
2. the water resources management,
3. the mitigation of water damages,
4. the jurisdiction of water authorities, and
5. the activity of water management companies as well.

## 83/1997 (IX. 26.) Government Resolution - The National Environmental Program

This program is actually a sustainable development framework program. The National Environmental Program is an intervention plan system for six years, which should result in the solution of the current environmental problems or the beginning of the solutions and the prevention of future problems.

## 2031/1998. (II. 13.) Government Resolution - The 1998 years' Provision Plan of the National Environmental Program

The Provision Plan was completed on the basis of the Parliament resolution. Every Minister and the political under-secretary of the Prime Minister's Office are responsible for the Plan. Deadline: continuous. The Provision Plan includes the applicable devices and the assessment of the steps in 1998.

## 2207/1996. (VII. 24.) Government Resolution - Directives of wastewater disposal and treatment program of the Hungarian settlements

The Government set up the guidelines of wastewater disposal and treatment program of Hungarian settlements to:

1. improve environmental conditions, and
2. develop the necessary conditions to join to the European Union.

This resolution includes a wastewater treatment and disposal program up to the year 2010.

54/1995. (V.10.) Government Decree - Utilization Order of Central Budget's financial aid of the wastewater treatment program for the capital and the county towns

The cities receive not refundable subsidy for building or enlarging of wastewater treatment plant in the framework of the Investment Aim-Program.

The Annexes of the decree include the documentation of professional program and the value of the subsidy (in per cent). The decree regulates the planning and utilization of subsidy, as well as the beginning and completion of investment.

152/1995. (XII. 12.) Government Decree - Necessity of environmental impact assessments, and detailed rule of the relevant official procedures
This decree orders the regulation of the device of preliminary environmental impact assessment studies, as well as the device of detailed environmental studies. Outlines the list of activities, where environmental impact assessment study is needed and the list of contributors as well.

## 36/1993. (V. 28.) Parliament Resolution - Government Program (1993-1994) to promote the healthy drinking-water supply of the settlements

The Parliament approved the 1993-1994 years' Government Program in such a way that should ensure the completion of drinking water supply in South-Great Plain, and should give yearly central budget subsidy for settlements having no public supply. The resolution states that the local government should be received financial aid for sewerage and wastewater treatment, which serve the protection of catchment areas. The resolution includes the list of settlements on the vulnerable subsurface drinking water resources.

## 1/1990. (XI. 13.) KTM Decree - General Environmental Protection Inspectorates and Environmental Protection Inspectorates

The tasks of the Ministry for Environment and Regional Policy are carry out due the Chief Environmental Protection Inspectorate and the District Environmental Protection Inspectorates, which are under its direction. This Decree determines the duties of the Chief Environmental Protection Inspectorate and the local Environmental Protection Inspectorates as well.

## 3/1984. (II. 7.) OVH Decree - Wastewater fine on water pollution

This decree introduces the determination of wastewater fine system, regulates the imposition and utilization of fund coming from wastewater fines. The limit values and unit amount of fine of water polluters, as well as the arrangement of water quality protection areas and other modifying factors are determined in Annex 1.of this decree. The Annex 1 was modified by the 33/1993 (XII. 23.) KTM Decree.

## 4/1984. (II. 7.) OVH Decree - Sewerage fine

This decree introduces the determination of sewerage fine system, regulates the imposition of sewerage fine as well. The decree is dealing also with the prohibition of harmful pollution inlet to the sewage systems. The limit values and unit amounts of fines, as well as the arrangement of water quality protection areas and other modifying factors are determined in Annex 1 of this Decree. The Annex 1 was modified by the 34/1993 (XII. 23.) KTM Decree.

## 9/1978. (V. É. 12.) OVH Instruction - Technical Regulation on the prevention of damages of accidental water pollution

This instruction is dealing with protection against exceptional - havarious - pollution of the surface and subsurface waters, and the prevention of damages. The prevention of damages in water quality - in case of waters and public hydraulic structures - should be carried out by the district Water Authorities. The instruction determines the necessary technical activities, regulate the duty of registration, and the way of the prevention of damages.

## MSZ 12749 Hungarian Standard - Quality of surface water, quality characteristics and classification, 1994.

The limit values of the five water quality classes, as well as the parameters to be measured, the list of water quality monitoring sampling stations and the frequency of measurements are determined by this standard. The Standard deals also with the classification system of the surface waters.

## 1997 LIII. Law - Nature Conservation in Hungary

Entered into force on 1 January 1997.

## Annexes

1. The water quality classification system. Hungarian Standard MSZ 12749
2. Number of water quality samples in selected stations, 1968-97. Danube system
3. Number of water quality samples in selected stations, 1968-97. Tisza system
4. Number of water quality samples for certain special water quality indices, measured since 1994 only (1997). Danube River system
5. Number of water quality samples for certain special water quality indices, measured since 1994 only (1997). Tisza River system
6. $\mathbf{9 0} \%$ duration values in selected monitoring stations (1988-1997). Danube River system
7. $\mathbf{9 0} \%$ duration values in selected monitoring stations (1988-1997). Tisza River system
8. Water quality classification on the basis of Hungarian Standard MSZ 12749. Danube River system
9. Water quality classification on the basis of Hungarian Standard MSZ 12749. Tisza River system
10. Bibliography

## 1. Summary

### 1.1. National Targets and Instruments for Water Pollution Reduction

The Hungarian National Environmental Program has general guidelines for water pollution reduction. The most important goals are that Danube and Tisza should reach the Class III level in all important parameters, the further pollution of irrigation waters should be stopped. The harm on vulnerable ground water resources should be decreased by better control of land uses and environmental conditions on the surface. The pollution of nitrate and pesticides from diffuse sources should be decreased in groundwater and sensitive surface waters. These targets have not been turned into direct ambient water quality objectives for the touched river bodies yet.
The technical instruments as Effluent Standards were fixed in 1984. Law differentiated six categories depending on the sensitivity of the recipient and the interest on the water uses. As the system was set up fifteen years ago, it can not fully serve the today's needs. The Hungarian effluent monitoring system is connected with the regular effluent compliance control. The effluent data coming from this legal procedure of effluent control and fining give not enough information on the real pollution load from point sources. As there are no reliable direct information on diffuse source pollution also, the weakness of data on pollution load gives the major bottleneck of water quality management planning today.
The monitoring laboratories belong to analytical inter-calibration system, and some of them have been accredited according to the ISO requirements too. Their professional level, instrumentation and quality assurance is close to the needs now. The data on effluent quality is open for the public.
The National Guideline of MSz 12749 as In stream water quality standards gives the general basis for classification of surface waters according their quality. There is no legal obligation for reaching water quality targets in the surface water stretches expressed according to these quality classes.
The legal tools as licensing, wastewater fine, general environmental check-up, environmental supervision, legal possibility for stopping the questioned activity are given by law. Their use is hindered by the eroded driving force of the fines connected to them, sometimes by the limited capacities of the involved authorities and by considerations of the further possibility on economic survival of the polluters.

### 1.2. Measures for Reduction of Water Pollution

### 1.2.1. Non-Physical Measures

The efficiency of the water protection is strongly affected by the existing legal possibilities of authorities involved in water pollution control. There is a common agreement on the necessity of development of the legal background and administrative capacities of these authorities. The actions connected to this issue are within the frame of the development program of Hungarian water legislation and the harmonization procedure with the EU environmental legislation.
There is an ongoing activity for the development of the national water legislation. Its basis will be the river basin and the integrated river basin management concept.
The proposed basic elements of the water quality management system can be summarized as

- Use related Water Quality Objectives (WQO), depending on the characteristic land uses and their water quality needs on the watershed,
- WQO-s should be harmonized with EC Directives,
- Clear transition of WQO-s into discharge standards,
- Prioritized, phased, achievable, affordable water quality management programs on watershed level, built up from local community wastewater management plans,
- Ownership for the objectives and improvement plans,
- Clear responsibilities and accountabilities,
- Efficient permitting and enforcement,
- Sound monitoring and reporting system,
- Simple, clear, efficient funding and charging systems,
- Adequate and technically competent staff for water pollution control,
- Legal framework to be given for the authority to provide and operate the system.

The crucial element of the concept is the full local involvement of all affected parties into a socalled Catchment Planning Commission for each catchment area. These Commissions would be responsible for setting up locally agreed WQO-s, for development management plans, preparation of annual reports on the progress of the local wastewater management plans. The Commission could work as a board drawn from representatives of all parties interested in water quality management on watershed level. The responsibility of the Commission covers water quantity and quality issues in order to provide an integrated approach to water resources management according to the EC Water Resources Framework Directive. It seemed to be unrealistic to follow strictly the full institutional consequences of the river basin approach immediately, it can be reached on a step by step approach in the future only.

The Environmental Charge would provide an assured revenue stream on a consistent basis. This charge would be levied on all dischargers according to the pollutant input allowed in their permits (giving possibility for them to apply for the decrease of their effluent standards when they want it). The environmental charge should cover the administrative costs of water quality management including the costs of the activity of regional water authorities and the Catchment Management Commissions. It could raise revenues for funding water protection investment programs also.

The water quality protection could not be managed without substantial contribution of the State. The State fund is needed for speeding up the pollution reduction programme, and for equalization of differences in affordability from local resources.
The EU-Directives will certainly have further impacts on water pollution control policy in Hungary connected with the ongoing legal harmonization procedure.

The majority of the EU directives have been built into the new proposal on Hungarian water protection legislation. The Framework Directive on Water Resources, the Nitrate Directive and the EU new agricultural policy, the Directive on integrated pollution prevention will likely result in further development in the national water protection policy. These possible new elements are

- The existing area distribution of the water- and environmental administration should be altered to a certain extent according to the river basin approach.
- Use related water quality objectives would be developed
- The existing effluent standards should be revised
- Register of protected waters should be set up
- The existing in stream monitoring system should be developed by putting the stress on monitoring based on bio-indication
- Specific local monitoring should be built up on protected waters, with specific regard for vulnerable groundwater resources.
- Watershed water quality management action programs should be launched
- Specific action programs could be started in areas where the nitrate concentration is higher than $50 \mathrm{mg} / \mathrm{l}$ from agricultural sources, additionally to the ongoing national program on protection of vulnerable groundwater resources
- The surface areas of vulnerable underground drinking water resources will belong to the protection should have priority against agricultural activities. This could have considerably effect on the existing agricultural production profile, or agricultural State subsidy system
- The introduction of the IPPC approach will generally change the existing effluent standards in the industry. The step by step approach is needed on this field
- The combination of the IPPC and in stream water quality approach can result considerable reduction of pollution in surface waters

### 1.2.2. Preventive Measures for Water Pollution Reduction

Having recognized that the shortages in environmentally sound wastewater management central programs were launched to reduce the pollution load mostly coming from municipal sources. These are:

## National wastewater collection and treatment program

was started for communities with the aim of reaching the $67 \%$ level of canalization for 2010. This program goes as two parallel subprograms as

- Sewage treatment program of Hungary for the smaller settlements and the
- Sewage treatment program of the Capital and the cities with county status. The basic reason for differentiation is the difference in the financial capabilities and necessary investment costs of the villages and big cities.

Separate programs were launched for the protection of existing and future well-field areas, as:

- Program on increasing the security of well-field areas in use and the
- Program on increasing the security of future well-field areas

The reason for differentiation is that the responsibility for the drinking water resources relies on the user of the resource, and the State is involved via the Sate grants only. In case of future water resources the total responsibility relies on the State today.

## Program on municipal waste management

was started also, as the big problems were understood on the environment and the human health hazard connected to the lack of sound waste management.

### 1.2.3. Remedial Measures

Centrally organized programs were started connected with several sensitive areas where the level of water contamination exceeds the tolerable level, or it is likely exceed it without a counteraction.

These are:

- Protection program on Lake Balaton
- Program on the great Hungarian Plain
- Program on increasing the water management conditions in the Mid-Danube-Tisza Region.
- Reduction of the environmental damages at Szigetköz region
- Program on environmental remediation of contaminated areas belonging to State responsibility
- Program on the rehabilitation of the abandoned old mines

## - National Environmental Health Action Program <br> - Program on National Ecological Network

These programs are mostly based on State grants, as the own contribution of the municipalities, or other responsible parties is not higher than $20-50 \%$ generally. There is a co-operation between the mentioned programs, as the application for grant of a community on wastewater treatment has priority development when it can be found on a vulnerable well-field area for instance.

### 1.3. Expected Regional and Transboundary Effects of Actual and Planned Measures

The transboundary effects of the Hungarian pollution reduction measures are determinated by the fact that the rivers leaving the country transport the pollution coming from countries, which are in upstream position compared with Hungary. The other important factor is that these rivers have big self-purification capacities.
The municipal point source pollution is regarded as the major factor of transboundary pollution from Hungary. The amount of treated wastewater led into surface waters will increase with the development of wastewater collection. The level of organic matters and microbial pollution will likely be decreased considerably with the decrease of the rate of untreated water led into the recipient. The nutrient load will likely stagnate due to the increase of wastewater treated biologically only on one hand, and decrease of the untreated wastewater at the other.

The industrial point source pollution could be kept on the existing level due to two contradictory tendencies. The industrial production will increase likely, which can increase the industrial water uses. The effluent standards would be strictened according to the IPPC approach.
The hazardous material content of the rivers with transboundary interest can be kept on low level also with the introduction of IPPC concept.
The agricultural diffuse pollution is low today due to the limited fertilizer and other chemical use. The possible intensification of agricultural production can cause increase in diffuse pollution as the pollution reduction in agriculture can be managed in indirect way mostly so it needs more time to reach pollution reduction again. This tendency can lead to the temporary increase of the nutrient load of surface waters in Hungary.

Further effort should be taken for increasing safety of the wetland areas and water related ecosystems with transboundary interest, as these areas have kept their nature close character due to the limited land uses connected sometimes with the used to be political uncertainties. Today there is a likely consequence of the increasing international co-operation in areas close to the national borders that the risk of damages increases for these important natural conservation areas (or areas worth for natural conservation).

## 2. National Targets and Instruments for Reduction of Water Pollution

### 2.1. Actual State of and Foreseeable Trends in Water Management with Respect to Water Pollution Control

### 2.1.1. The Major Problems of Water Pollution in Hungary

## Danube

As it can be seen from Part C of the National Reiews, the quality of the Hungarian waters can be characterized by the strong dependency on the upstream land uses and activities, home pollution loads from public, industrial and agricultural sector, and natural self purification capacity of the different surface waters as recipients.

Danube comes with the used waters of the population living on the watershed in Germany, Austria Czech and the Slovakia Republics. The water quality is usually in the III class according to the Hungarian water quality classification system. The parameters of the oxygen balance show a relatively good picture, the concentration of nutrients is in the middle range. The phosphorus concentration is regarded as limiting factor from the point of view of eutrophication. The average concentration is around $0,3 \mathrm{mg} / \mathrm{l}$, what is tolerable in flowing water, but it can cause eutrophication problems in standing, or slowly flowing water bodies in oxbows in the Szigetköz, RáckeveSoroksár and Gemenc region.

The Szigetköz gravel terrace area is a very important drinking water resource that is in close connection with Danube, and sensitive to the background pollution coming from the different activities of the population living on the terrace also.

Gyõr town lies at the eastern end of the Szigetköz area, along the Hungarian-Slovakian border section of the river. The level of wastewater treatment is mechanical only today. The number of the population is 227,000 . The increase of the capacity of the treatment, extension of the treatment technology with biological unit, and sludge management is regarded as high priority.
Budapest gets its drinking water from the bankfiltered water of the Szentendre and Csepel islands, at the bank of Danube. There has been built a drinking water supply system with about 1.2 million $\mathrm{m}^{3} / \mathrm{d}$ capacity. The actual daily consumption has decreased to $650,000 \mathrm{~m}^{3} / \mathrm{d}$, due to the tendency of decrease the State subsidy in the drinking water fee (See chapter B also!). The well-field area is very sensitive to the water quality in the river, so the water quality objectives should reflect this important water use. The drinking water quality requirements can be fulfilled via chlorinating only in the Szentendre area today. Iron and manganese removal and activated carbon treatment is needed at the Csepel Island, due to the background contamination connected with the intensive land uses on the Island.

The Ráckeve-Soroksár oxbow is a recreational area near to Budapest. The neighborhood is a popular suburban area. A clear demand can be experienced for the use of this water body for bathing, water related sports and angling. The latter can be fulfilled generally without any water quality conflict. The water quality in the oxbow is basically determined by the fact that the phosphorus content of Danube generally reaches the $0.3 \mathrm{mg} / \mathrm{l}$ level in this section of the river. This concentration is high enough for alga blooms in summer conditions in this practically standing water. Additionally this oxbow is a recipient of the South Budapest wastewater treatment plant with the capacity of $70,000 \mathrm{~m}^{3} / \mathrm{d}$. The plant is being extended with an advanced treatment technological unit.

The level of wastewater treatment is about $20 \%$ today at Budapest. As it was discussed in Part C, the untreated wastewater strongly influences the microbiological water quality of Danube. The parameters of oxygen balance are acceptable here due to the high selfpurification capacity of Danube.

Dunaujváros is an industrial town 80 km downstream from Budapest with 57,000 inhabitants. The industrial waters are properly treated, but the town does not have any public wastewater treatment facility today. The problem belongs to the high priority class according to the priority classification system described in Part C, but the effect of Budapest overwhelms the pollution from the town (i.e. the water quality is worst in the upstream monitoring section than in downstream to Dunaujváros, as an overall balance of the selfpurification capacity of the river and the pollution load from the town).

The Gemenc area belongs to the Danube-Dráva National Natural Conservation Park, due to the specific water related ecosystem found there. This area suffers not mainly from the water quality, but the water quantity problems. The upstream interferences into the natural flow characteristics of Danube caused important changes of the life conditions of the biota. It is known that the Austrian dam systems decreased the gravel transport of the river. Additionally, big gravel mining activity was allowed in Budapest area. Consequently, continuous deepening of the riverbed can be experienced. This procedure endangers not only the bankfiltration water resources at Budapest, but also the natural life conditions of the valuable water related ecosystem of Gemenc and the DanubeDráva confluence.

## Tisza River

Tisza comes to Hungary as a clean river from Ukraine, but it is strongly loaded with the pollution carried by the Szamos, Kraszna from Romania, and in some cases as accidental pollution of the Bodrog from Slovakia Republic and Ukraine. The quality of the river is worst from this point, compared with Danube. Alga booms can be experienced in strong and long hot weather condition in the backwaters of the Tiszalök and Kisköre dams. The high alga content can cause problems for the Balmazujváros and Szolnok area, as the surface water serves as raw water for drinking water supply in these regions.

The Sajó was another mayor pollutant of Tisza one decade ago, due to the strong industrial activities on the watershed in Hungary and Slovakia Republic both. The water quality has improved for today due to the economic recession and change of the industrial production profile. There can be a danger of new pollution increase when the economic development speeds up again.

The reservoir of the Kisköre dam has become a natural conservation area owing to the valuable water related ecosystem developed there. The reservoir can be characterized as a shallow lake, or even as five shallow lakes in strong interrelationship with Tisza flowing through. Conflicts emerge in several cases with the harmonization of the different interests, especially between the natural conservation requirements and tourist development plans. This conflict seems to be manageable on its today's level.

The lack of wastewater treatment in Szolnok, with its 76,000 persons' population is a high priority problem according to our ranking system. Details can be found in chapter B.

Maros comes into Tisza with high level of pollution mostly from Rumania increasing the pollution transport of the river considerably directly above Szeged town. This problem has a transboundary character, as only $15 \%$ of the river length is found in Hungary.

Szeged town is an another high priority pollution source with its 166,000 inhabitants and total lack of wastewater treatment (see chapter C also!).

The fact that the reservoir of the dam of Tiszabecse in Serbian Republic is directly below the Maros-Tisza confluence and Szeged town, increases the sensitivity of the water body there. Extreme water quality conditions are not unusual here at summer. This issue has a transboundary nature.

## Big shallow lakes

The vulnerable big shallow lakes cause high priority water quality problems too. The lake Balaton as popular tourist area worth for international interest is endangered by eutrophication. Today the problem is in the middle of public and professional interest. The limiting factor of the nutrient balance is the phosphorus. Strong efforts have been done for decreasing its load into the Lake, but the results show limited success due to the buffer capacity of the sediment and the limited outflow of the Lake. A pollution reduction program is being organized with international help on the Lake Balaton watershed. The major bottleneck of the program is the big number of the interested parties in the action program and the diversity of their interest. As the bigger pollution reduction investment projects mostly have been solved by the State for today, the problems of the smaller background settlements has remained back.

Velence Lake is a popular tourist and recreational resort on halfway between the Balaton and Budapest. It suffered from water quality problems connected with the limited fresh water supply of the Lake. The situation became so serious in the last several dry years, that the State had to interfere, and finance the costs of artificial water supply. This problem could emerge again depending on the water conditions in the Lake Velence.

## Big pollution sources with small recipients

There are very characteristic surface water problems in areas where big towns have recipients with limited dilution capacity. Chapter C discusses them in point 2.1. and Figure C 2.1. gives the reference for them, so we account them briefly as:

| Town/polluter | Recipient |
| :--- | :--- |
| Sopron | Ikva creek |
| Veszprém <br> Nike industrial plant <br> Székesfehérvár | Séd-Nádor water system |
| Oroszlány <br> Tatabánya <br> Tata | Általér creek |
| Kaposvár | Kapos river |
| Pécs | Pécsi Víz creek |
| Eger | Eger creek |
| Nyiregyháza | Lónyai Canal |
| Kecskemét | Excess water canal |

We can state that
$>$ All of the polluters have their wastewater treatment plant.
$>$ Some of them should be modernized as at Sopron, Veszprém, Székesfehérvár, Eger
$>$ Others work according to the authority requirements.
$>$ NIKE produces very strong hardly degradable wastewater, which causes considerable pollution load even after the treatment. The wastewater treatment plant works with fairly good efficiency, but it needs to be modernized.

It is also common that the recipients are strongly loaded by nutrients, due to their low dilution capacity, and they endanger the downstream water uses. The ongoing activity, when authority starts to set up water quality objectives for the recipient listed above, would likely lead to strictening the existing effluent quality standards.

## Groundwater resources

Hungary gains $95 \%$ of its drinking water from groundwater as it was discussed in Part A. More than $65 \%$ of this water resources is vulnerable (i.e. more or less dependent on human activities). The safety of these groundwater resources is a number one priority issue on national level in Hungary. It is clear that the transboundary effects of groundwater contamination are limited. In spite of this fact we have to discuss two important issues in cross-border context.
$>$ The bankfiltered water resources of the Szigetköz and Budapest area are sensitive for accidental pollution coming from home and foreign upstream sources both.
$>$ The ancient gravel terrace of the Maros is an important vulnerable water resource. More than $60 \%$ of this natural underground unit belongs to Romania. Its importance is increased by the fact that the alternative deep layer water resources have unacceptably high natural arsenic content in the region.

### 2.1.2. The General Picture of Water Pollution in Hungary

The following basic statements can be done if we want to characterize the actual situation in Hungary in the field of water pollution.

## Industry

The Hungarian water authorities were relatively successful in the field of industrial pollution reduction in the last 30 years, due to the fact that industry has became relatively independent from the State. The new economic mechanism was introduced in 1968, when the owner of industrial plants basically remained the State, the responsibility for supply the population with goods retained with the State. The industrial factories have became independent in their market activities, and responsible for the economic results of their activities at the other hand (i.e. the State was not directly responsible for industrial water pollution.)

There was no possibility for building a new industrial plant without water treatment plant from that time. The authority was free for setting up effluent requirements according to its professional judgement, and build up point source pollution control systems at the existing industrial plants also. As a consequence today all the industrial factories have their own wastewater treatment or pretreatment facilities. (Pre-treatment is needed when a factory is connected to public sewer.)

We can state that these facilities are not always good enough according to the existing pollution load, effluent requirements, etc., but the basic elements of the treatment technology exist usually. Perhaps we are not wrong when stating that water protection administration was relatively successful in the field of industrial pollution reduction.

The political and economical changes have given dramatic changes in the industrial profile and in the circumstances of pollution reduction also by the beginning of the nineties.
> The market of the industry changed as the used to be Soviet market practically collapsed owing to the financial problems in these countries.
$>$ The big industrial centers were not able to accommodate themselves to the western market immediately, so they found themselves in economic crisis from one day to the other.
> The State was not able to rebuild the industry from the existing financing sources. Privatization started, what changed the product profile, the technology, working discipline in the old factories.
> It was another consequence of the privatization that the big factories dismantled into small limited companies. The changes of ownership were not always properly tracked by the environmental authority. The responsibility for water pollution can sometimes be lost easily along these rapid changes.
> All the Hungarian licensing procedure was build up with regard to big new industrial development projects, and to a smaller extent considering the possible changes inside existing plants. The legislative tools were not efficient enough for managing this situation. (As an example: the cultural building with theatre room of a big company was sold to a limited company, and they used the building as a pesticide storehouse for years, without any co-operation with the authorities.)
> Some big heavy industrial plants were not able to survive even via privatization. They had to stop their activities. The pollution decreased on one hand, but a new danger of contamination has emerged from the abandoned, corroded, not properly guarded facilities.
> The new industrial plants usually start their activity with good willingness to accept environmental regulation, especially when the majority owner is a big international company.

As a general consequence of the changes of industry the pollution decreased from industrial sources, but increased the risk of big environmental pollution incidents due to the lower level efficiency of water pollution control.

## Municipal sector

The level of wastewater collection and treatment remained much behind the municipal water supply as it was described in Part A. This situation is a result of a contradictory development tendency that began on one hand with the old ages, when the need of wastewater treatment was not completely understood even in the case of big cities. On the other hand in the middle of fifties political decision was adopted to increase the life conditions of the population by launching waste housing programs. Easy loans were available with the requirement of bathroom in the houses. The housing program was accompanied with public water supply, but not with wastewater collection due to the high cost consequences. The increased water consumption resulted in bigger amount of wastewater infiltration, so the nitrate content of the remained individual wells settled on the shallow groundwater had become unacceptably high. This effect speeded up the public water supply too.
The unsustainable situation had become clear by the beginning of the eighties, and a decision was adopted what was very characteristic for that political system. The new houses could get the licenses for use only when proving the existence of closed wastewater storage tanks. Thousands of theoretically closed storage tanks were built at that time without any control capacity by the side of the licensing authority. The level of canalization remained behind the public water supply. The pollution of shallow groundwater was not a priority issue due to the usually good possibilities for
good quality drinking water production from the deeper layers. In case, when the water resources were not so advantageous, long distance utility systems (so called regional systems) were built with no regard for the economic consequences of these types of solutions.

The costs of water production were strongly subsidized so the low cost drinking water production was not an important issue for the population. Wastewater collection was important for them only in case where there were no proper soil conditions or high level of the groundwater table hindered the wastewater infiltration. The results of these tendencies were shown in Part A, as the utility gap of $95 \%$ public water supply was compared with $43 \%$ wastewater collection.
It should be added that the phenomena of the so called utility gap have a misleading meaning, expressing inclusive a long term goal for $100 \%$ canalization. The long-term target is $67 \%$ wastewater collection according to the National Masterplan on Wastewater Management, and the remaining part of the population will manage their wastewater by environmentally sound individual facilities.

## Agriculture

Distinction should be made when examining agricultural pollution, depending on the type of sources. The agricultural point sources are generally handled as it was described in the case of industrial sources. The authorities have the legislative tools and administrative capacities for controlling them.
There is no available statistical data on diffuse pollution from agriculture in Hungary. The drastic changes in ownership, State subsidy policy and market conditions connected with the political changes have resulted in uncontrollable situation in this sector these days. The most important tendencies of changes in the agriculture are as follows:
$>$ The majority of the former co-operatives was turned into small privately owned agricultural lands via the compensation procedure, usually with a smaller land size than it would be necessary for economic cultivation, or to give a sound financial basis for a family. A tendency can be experienced nowadays as the former co-operative having turned into a share holding company rents the land from the new owners. The uncertainties of the ownership do not give good basis for investment programs. The lack of capital in agriculture is very characteristic. Loans are available, but the owner can not give enough guaranties. The high level of inflation ( $15 \% / \mathrm{a}$ in 1998) is disadvantageous for long term investments.
> The relatively high level of fertilizer utilization ( $400 \mathrm{~kg} / \mathrm{ha}$ ) in the eighties has dropped down to $40 \mathrm{~kg} / \mathrm{ha}$, as a consequence of the decrease of the State subsidy in agriculture. The same refers to other agrochemicals (pesticides herbicides) also.
> The rate of irrigated land has dropped down due to the lack of State subsidy also and the weak possibilities for investment into new irrigation machinery.
> The big animal farms with water dilution manure handling technologies having developed in the last decade mostly stopped their activities in connection with financial problems. The number of pigs and cows has dropped down to about half of the maximum level.

These tendencies resulted in big decrease in agricultural water pollution. There are some other factors, which have increased the risk of water pollution in agriculture:
> Small private animal farms appeared around the villages with not bigger capacity than 100 animals, without any license for their activity. The regional environmental authorities are not able to control them. The local environmental control is very weak owing to the limited administrative capacities, and certain counter interest can be experienced sometimes as local government is interested in short term economic development. It is not unusual that they use water feedlot cleaning technologies causing definite risk for drinking groundwater resources, or smaller creeks and canals.
> The soil amelioration activities has dropped dramatically due to lack of long term interest in soil protection, unsecured ownership conditions, shortages of personal knowledge, lack of State subsidy.
$>$ The condition of the excess water collection canal systems is very poor today. This issue was very important in the Hungarian agriculture one hundred years ago as about $25 \%$ of arable land areas is below the flood level with $1 \%$ probability. Originally local water associations organized from the owners were responsible for their maintenance, but the bigger part of responsibility was taken away by the State later. The new owners do not really feel the importance of these drainage systems especially having the experiences of the several last dry years only.

The figures available on non point agricultural water pollution are estimations mostly based on literature, adaptation of other countries experiences, or by comparison of the total pollution load of the river and the amount of pollution load from the known point sources. There is an agreement among the involved parties that the importance of non point source pollution increases with the development of wastewater collection and treatment in other sectors. This statement is extremely important on the watersheds of the big shallow lakes. As an example it is estimated that $70 \%$ of the total phosphorus load reaching Lake Balaton from the Zala watershed (about $30 \%$ of the total Lake basin) is originated from agricultural diffuse sources.

### 2.2. National Targets for Water Pollution Reduction

The Hungarian National Environmental Program has general guidelines for water pollution reduction, as it was introduced in Part A, point 7.1.
> Danube should reach the Class III level, according to the MSZ 12749 water quality standard, regarding hazardous materials and microbiological parameters,
> Tisza should reach the Class III level in all parameters,
> The big lakes should reach the Class II level, and Chlorophyll-a should be less than $75 \mathrm{mg} / \mathrm{m}^{3}$,
> The increase of salt and toxic material content should be stopped in irrigation waters. The limits of salty wastewater led to understanding that recipients should be strictened further.

These basic targets have not been turned into ambient water quality standards for the touched watercourses yet. As a consequence the effluent quality standards do not fully reflects the requirements coming from the national targets.
The safety of groundwater resources is also a number one national environmental issue. The basic targets of the National Environmental Plan are as follows:
> Measures should be taken for the sustainable use of available resources with on site disposal and higher recycling of purified used waters.
> The water balance between the use of groundwater and natural replenishment should be improved with better control of the water uses and other measures on areas with sinking groundwater table. The existing pressure decrease should be stopped by moderation of the exploitation of groundwater resources.
> The harm on vulnerable ground water resources should be decreased by better control of land uses and environmental conditions on the surface.
> The pollution of nitrate and pesticides from diffuse sources should be decreased.
> Special attention should be afforded for regions where the natural water quality (i.e. natural Arsenic content) of the drinking water exceeds the limits of the WHO Standard.

The programs attached to these targets are described in Parts A and B. As it can be seen three national wastewater collection and treatment program have been launched for communities, and a special one for big cities. Separate programs are elaborated for the protection of well-field areas. These programs are mostly based on State grants, as the own contribution of the municipalities is not higher than $20-30 \%$ generally. There are specific programs on several sensitive areas as Lake Balaton watershed, Szigetköz area, Great Hungarian Plain fully, or partly concentrated on water management issues. The other group of national programs is targeted on important environmental issues as the management of the environmental problems left behind by the used to be State owned factories, or Russian troops, decrease of the risk of municipal waste disposal, etc. These programs are fully counted and described in Part A and B.

### 2.3. Technical Regulations and Guidelines

### 2.3.1. Effluent Standards

The concentration limits fixed in the $3 / 1984$ Governmental Decree on effluent discharge fines are regarded as effluent standards in Hungary. There are six categories differentiated in the Decree depending on the sensitivity of the recipient and the interest on the water uses. As the system was set up fifteen years ago, it can not fully serve the today's needs. There are proposals for its further development. The decree is introduced in Annex B.1 (ref.11.)

The regulation gives the possibility for setting up specific individual effluent standards depending on local conditions. Basically this possibility could give a good flexibility for the system. The problem is that the environmental authorities should be very cautious with this tool, because they are not always able to defend their decision in the case of an appeal, as there are no obligatory in stream water quality standards, or obligatory water quality targets in Hungary today. As a consequence, this possibility is used mostly not for strictening, but for loosening the standards written in the Decree.

The major problems with the regulation are in connection with the changes of importance of the water uses to be saved. There are area categories where the requirements are not strong enough compared with the basic environmental needs. The closed list of contaminant parameters in the Decree (i.e. in the case when a new chemical appears in the water body, the authority has limited possibility for fining.) can not give enough room for local considerations.

The Ministry for Environment has the opinion that the effluent standard and fining system should be differentiated in near future. The new effluent standard system should reflect the needs of the water quality target in the recipient on one hand, and the requirements of BATNEEC, or BAT depending on the type of pollution on the other.

### 2.3.2. Monitoring

The ambient water quality monitoring system is described in Part C, so we introduce here the Hungarian effluent monitoring system.
The effluent water quality control is based on the Governmental Decree on wastewater fine mentioned before. Consequently the effluent monitoring is connected to that Decree also. The laboratories of the regional environmental authorities check the effluent water quality from two to four times in a year, in the framework of a legal procedure. The sampling is normally carried out together with the water polluter as a part of the legal procedure. The sample is divided into two parts and shared. The polluter has the right for doing parallel analyses and to use the results in the case of a possible appeal.

There is possibility for self-monitoring on the basis of agreement with the environmental authority in case of having proper laboratory and professional basis. The big municipal wastewater companies commonly use this self-monitoring as they are prepared for these type of laboratory tests, in connection with the task of controlling the industrial and business companies connected to their sewer systems.

The environmental and self-monitoring laboratories belong to an analytical inter-calibration system, and some of them have been accredited according to the ISO requirements too.
There used to be uncertainties whether the data gained in the effluent monitoring procedure is open for the public or belongs to the polluter's privacy, and the polluter can decide on their use outside the legal procedure. The Ministry for environment has stated in February 1998 that these data are information with public interest on the state of environment, so they should be open and free for the public without proving any direct interest for having them. The environmental authorities are the so-called data owners, and hey are allowed to get the costs of multiplication only (Xerox, etc.).

There is a general agreement among the interested experts that the existing monitoring system is too weak compared with the professional needs. The limited number and reliability of the effluent monitoring data give the major bottleneck of the water quality planning procedures in Hungary. The major problems are:
> The 2-4 samples in a year can not give realistic picture on the pollution load from the given source.
> As the sampling goes with the co-operation of the polluter it is not impossible that he can do some measures inside the factory for improving the water quality temporarily in the time of sampling. Sometimes it is not too easy to find strong correlation between the measured effluent quality and the figures calculated from the pollution load change upstream and downstream to the point source pollution.

The proposals of development on effluent monitoring suggest to the Ministry for Environment that the self monitoring could be obligatory for the bigger polluters, the minimum number of sampling would be 12 up to 52 in a year. The existing capacity of the environmental laboratories would be maintained for controlling the self monitoring system, and serve the legal procedure described before.

### 2.3.3. In Stream Water Quality Standards

The National Standard of MSz 12749 gives the general basis for classification of surface waters according their quality. This standard was introduced in Annex 1 of Part B. The evaluation guidelines give figures for "general" water quality taking into consideration the requirements of the important water uses in Hungary. The evaluation based on this guideline is proper for giving information for the decision-makers, but there is no legal obligation for reaching some water quality targets expressed in certain quality classes.

### 2.4. Expected Impacts of EU-Directives to Water Pollution Control

The majority of the EU directives have been built into the new proposal on Hungarian water protection legislation. The Urban Wastewater Directive was taken into consideration in the National Masterplan on Wastewater Management also. There are some other EU regulations which are expected to result further development in the national water protection policy. These are the Framework Directive on Water Resources, the Nitrate Directive, the EU new agricultural policy, the Directive on integrated pollution prevention.

## The Framework Directive

The requirements of the Directive were integrated into the proposal on the development of the Hungarian water legislation described before. The basic goal was to avoid any contradiction with the EU Directive at that time. There remained some issue, which should be considered also.
> The existing area distribution of the water- and environmental administration does not follow consequently the river basin approach. Changes are not unlikely in the district areas of the regional water authorities.
> The "good water quality" has not been defined on the water bodies. Use related water quality objectives would be developed. This procedure would lead to the water quality target systems with obligatory legal force. As a consequence all the existing effluent standards should be revised.
> Reliable inventory should be developed and maintained on the emission sources causing harm for the water environment.
$>$ The Register of protected waters should be set up according to the EU Directive that includes the groundwater resources, habitat of species with economic importance, recreational waters, bathing waters, water bodies sensitive for eutrophication, environmentally valuable water related biotops.
> The existing in stream monitoring system should be developed according to the attachment of the Directive. The existing chemistry oriented monitoring system should be altered to be closer to hidrobiology. This monitoring should be developed also in order to support the catchment planning procedure. Specific local monitoring should be built up on protected waters, with specific regard for vulnerable groundwater resources.
> The water protection would be based on watershed action programs. The actions, responsible parties, deadlines are to be fixed there. It can not be seen clearly now, who could be the responsible party in Hungary, as about $80 \%$ of the water protection investment costs are born by the State now. We are willing to see the existing water protection programs as additional sector programs to the catchment management programs that should be developed.

## The Nitrate Directive

This Directive requires specific action programs in areas where the nitrate concentration is higher than $50 \mathrm{mg} / \mathrm{l}$ from agricultural sources, in harmony with the EU framework directive. The examination of this Directive has just started in Hungary. The national legislation gives first priority to preventive protection of the vulnerable groundwater resources independently form their today's level of nitrate pollution. Decision is needed on the sensitive areas in Hungary according to the context of the Nitrate Directive. It seems to be likely that the protection of Hungarian drinking water resources needs stricter regulation compared with the EU Directive, and the existing care on groundwater in other areas should be increased further.

## Harmonization with the EU agricultural policy

The agricultural activity is categorized into three groups as intensive, extensive and protection oriented activity according to EU guidelines. The designation of these categories has not happened yet in Hungary. It seems to be likely that the supply areas of the vulnerable underground drinking water resources will belong to the protection zones, where environmental protection should have priority against agricultural activities. This categorization could have considerably effect on the existing agricultural production profile, or on State subsidy system.

## Introduction of the Directive on Integrated Pollution Prevention Concept

The industry is controlled according to the existing wastewater fine decree as it was described before. This decree relies on the end of pipe concept, affording minimal care to the procedures inside the factory. The introduction of the IPPC approach will likely completely change the existing situation. It seems to be likely that its adaptation can be done on a step by step approach.

The combination of the IPPC and in stream water quality approach can give the necessary level of protection for the Hungarian surface waters, and results in considerable reduction of pollution load reaching the surface waters from the industry.

### 2.5. Law and Practice on Water Pollution Control

### 2.5.1. Licensing

The activity of the water user should be based on water licenses in Hungary. A detailed documentation is needed for the license for construction to show the aim of the water use, the planned technology, where the water is needed, the effluent quantity, planned wastewater treatment technology, proposed effluent quality standards, the suggested recipient and all the other important facts what are relevant for decision making.

The licensing authority is the regional water directorate. All the interested other authorities have their role in the procedure. They give their statement what should be taken into consideration obligatorily by the water authority. The regional environmental authority gives the effluent quality standards for instance.
The investment program will follow the license strictly, or the license must be modified in the case of emerging new facts, or changes in the investment program. The license is valid for undecided time according to Hungarian law, but the licensing authority has the right for revision on water management-, or environmental ground. Compensation is possible when the change is done for the advantage of one other water user. There is no compensation when the change was a consequence of environmental needs.

Environmental impact assessment is obligatory for a specific list of activities by law (i.e. wastewater treatment plant with bigger capacity than $5000 \mathrm{~m}^{3} / \mathrm{d}$ ). The results of this procedure are settled down in an environmental permit.

There are small local objects as septage tanks and wells on shallow groundwater, which are not deeper than 30 m for individual use of the inhabitants that is subject of licenses given by the local government. The enforcement of this regulation is weak, due to the limited professional and enforcement capacity of these local authorities.

### 2.5.2. Enforcement Tools

The environmental and water authorities have several enforcement tools for controlling the activities of the water users, or polluters. These are the wastewater fine, the possibility for occasional general environmental check-up, environmental supervision and action program connected to that, stopping the questioned activity partly, or totally. We describe in this chapter these legal tools in more detail for the better understanding.

## Wastewater Fine

We have mentioned that the $3 / 1984$ Governmental Decree on the wastewater fine gives the possibility for fining the wastewater discharger in case of exceeding concentration of certain materials settled down in the water license. The fine comes from the pollution load calculated on the basis of the part of measured concentration, which is above the effluent limits in different parameters and the water quantity. The good estimation of water quantity is not always easy, as there hardly can be found measurement units at the wastewater outlet in Hungary. Consequently the estimation goes on the basis of water consumption, which is usually measured. The decree gives a multiplication factor from 0,1 up to 2,5 expressing the environmental interest on pollution reduction, harm caused by excess pollution. There is another multiplication factor, the so called "progressivity multiplier" which depends on the length of illegal situation (in years).

The driving force of the wastewater fine is limited due to the fact that the fine has never been comparable with the costs of pollution reduction. The bigger part of the collected money supports the Central Environmental Fund, the other 30\% gives financial support for the touched local government (but without any obligation for using the money on water pollution related issues).

## General Environmental Check-up

The environmental authorities have the right for launching complex environmental check-up in their jurisdiction. This thorough on spot examination covers all mediums and all fields of activities. The results of these actions are written into protocols, where the necessary measures and deadlines are usually fixed in the form of an action program.

## Environmental Supervision

This tool is usually used when the general check-up mentioned before shows the probability of uttered danger on the environment. The environmental authorities have the right to oblige the "users of the environment" for contracting from they own financial source with accredited auditor companies. Detailed examinations come usually in these cases, where the real extent of pollution is investigated by drilling, sampling, analytical work and calculated mass balances.

The result of the accepted report is usually a remediation action program. This program is financed by the polluter with the control of the environmental authority, or that of the entitled auditor consultant. Financial help is available from the Central Environmental Fund on application basis.

This relatively new tool has came from the Environmental Bill in 1995. Its efficient use is hindered now by the lack of detailed regulation on some connected issues. It is not clear for instance, what should happen with a polluter who neglects to hire the auditor on the ground, that he has not enough financial source for the audit. Whether the pollution action program should be implemented when there is no any environmental grant for helping it.

## Stopping the questioned activity

The environmental authority has the right to shut down partly, or totally the activity, which causes a proven danger for the environment, and the responsible polluter does not show enough capability, or willingness to implement the necessary countermeasures.

This tool can be used in extreme cases only, with special regard for the fact that in the case when the polluter loses its financial capacity in connection with the environmental burden and goes into bankruptcy the pollution remains back for the State at the very end of the procedure.

### 2.5.3. Development of the Water Legislation in Hungary

As it was mentioned the existing legal framework fails to address the problems of water protection properly. There is an ongoing procedure for the development of the national water legislation. MERP and MTTCWM adopted the concept in principle. The legal proposal is introduced in Annexes, so we give only a short summary here.

The basic element for water quality management and regulation is the river basin according to the proposed new water legislation. The new legislation targeted the application of the world-wide experiences of integrated river basin management to Hungarian circumstances.

The basic aims are to secure the institutional background for avoiding the deterioration of the receiving water qualities, determination of the desired water quality improvements, incorporation of the EC Directives, the development of a sustainable water quality protection strategy, specification of required effluent quality through a system of individual, time related discharge permits, effective enforcement to ensure permit compliance. Additionally a proposal was needed for a more efficient system of revenue collection for water pollution investments and for financing partly water protection control activities.

The basic elements of the water quality management system can be summarized as
> Use related Water Quality Objectives (WQO), depending on the characteristic land uses and their water quality needs on the watershed. The WQO-s should be harmonized with EC Directives,
> Clear transition of WQO-s into discharge standards,
> Prioritized, phased, achievable, affordable water quality management programs on watershed level, built up from local community wastewater management plans,
> Ownership for the objectives and improvement plans,
> Clear responsibilities and accountabilities,
> Efficient permitting and enforcement,
> Sound monitoring and reporting system,
$>$ Simple, clear, efficient funding and charging systems,
$>$ Adequate and technically competent staff for water pollution control,
$>$ Legal framework to be given for the authority to provide and operate the system.
New institutional machinery is necessary to be developed what is capable to define the catchment management plans. The crucial element of the process outlined before the full local involvement so that the objectives and plans should be "owned" by the communities, industries, water users etc. affected by any resulting proposals. Catchment Planning Commissions would be established as new bodies having the responsibility on the implementation of the action plans for reaching the objectives for each catchment area. The financial basis of their activity would be a part of the water discharge fee collected in the watershed, and resources having won from the central funds by application.
These Commissions would be established by the responsible ministry, and accountable also to this Ministry. They would be responsible for setting up locally agreed WQO-s, for development management plans, preparation of annual reports on the progress of the local wastewater management plans. The Commission could work as a board drawn from representatives of all parties interested in water quality management. The responsibility of the Commission covers water quantity and quality issues both, in order to provide an integrated approach to water resources management according to the EC Water Resources Framework Directive.

It was experienced that the level of responsibility to be delegated to the Commissions is a sensitive issue for the existing administrative bodies, so the legal proposals limited themselves for the proposition of a partial river basin approach. It seemed to be unrealistic to follow strictly the full institutional consequences of the river basin approach immediately, it can be reached on a step by step approach in the future. As a consequence three regional environmental- and water authorities could help these associations with coordinative work and control the results of their activities in their authority jurisdiction.

The Environmental Charge would provide an assured revenue stream on a consistent basis. This charge would be levied on all dischargers according to the pollutant input allowed in their permits (giving possibility for them to apply for the decrease of their effluent standards when they want it). The real effluent load could be calculated on the results of self-monitoring. The environmental charge should cover the administrative costs of water quality management including the costs of the activity of regional water authorities, the Catchment Management Commissions. It could raise revenues for funding water protection investment programmes also.

It should be emphasized that water quality protection could not be managed without substantial contribution of the State. The State fund is needed for speeding up the pollution reduction programmes, for equalization of differences in affordability from local resources. The State funding philosophy should be based on the National Action Programme for Wastewater management, which is part of the National Environmental Programme. The subsidy mechanism should have a clear, auditable decision procedure with close monetary control.

## 3. Actual and Planned Projects and Policy Measures for Reduction of Water Pollution

### 3.1. Non-Physical Projects

As we described before clear concepts exist on the needs and directions of the development of legislative background of water protection in Hungary in connection with the economic and political changes and the requirements of the EU harmonization. We can describe this activity as the implementation of a well-defined non-physical programme on water quality protection.
There is a possible necessary non-physical project to accommodate the institutional administrative and financing structure to the new water legislation. It can be felt that the goals in this area are defined with much more little clarity.
Project proposal is available on the development of the national in stream monitoring system, prepared with the help of PHARE. This concept was prepared before the availability of the Draft EU Framework Directive, and the appearance of watershed management plans was not clear at the time of monitoring concept preparation. The further development of the proposal on surface water monitoring is necessary with regard the EU Framework Directive.
Other non-physical projects could be necessary for increasing local and regional awareness on water management issues. The watershed planning activity needs the real involvement of the different interest groups on the watershed. That is a common experience that the local interest hardly goes beyond the level of the drinking water fee today. It seems to be not unlikely that the professional capacities available locally will give the limiting factor in organizing the Watershed Planning Associations mentioned before.
The described non-physical projects are on the level of proposal today. A general water quality management strategy could put these projects under one umbrella.

### 3.2. Physical Activities for Water Pollution Reduction

There are different central programs on water pollution reduction in Hungary. Their targets are mostly well defined and differentiated, but they are not always strictly defined regarding their technical content and financial consequences. These programs are described in the chapter 7.1. of Part A. We try to explain their background instead of repeating them.
Generally we can find hot spots where there are intensive, hazardous activities in sensitive, vulnerable areas. We can describe them as
$>$ hot areas, where the sensitivity of the water environment is high. These are the well-field areas of the vulnerable groundwater resources, catchment areas of the big shallow lakes, watercourses with high pollution load and small self-purification capacity.
> hot sectors where the level of water pollution reduction is well behind the acceptable level or the shortage of good management gives a considerable risk on water pollution. The public sector can be identified as a major hot sector, and the agriculture to a certain extent.

We have chosen the pollution sources to be included into the group where project files would be prepared from the list of national hot spots, where transboundary impact is possible. We call them as "very hot spots." It should be noted that the real transboundary harm should be proved later on some way of modeling, etc. The map showing these possible very hot spots can be seen as figure 2.2. in Part C.

The Hungarian central programs work basically on application basis. It means that the technical content is not defined, only the systems of priorities are fixed. The responsibility of the implementation relies on the applicant. The authority cannot oblige the polluter for application for the grant, but he can increase the interest via indirect interference. In case of deciding on the grant allocation the connection of the applicants with the hot areas and hot sectors are weighted in the judgement.

### 3.2.1. Reduction of Water Pollution from Municipalities

It is recognized that the shortages in sound wastewater management central programs were launched to reduce the pollution load mostly coming from municipal sources.
The national wastewater collection and treatment program is based on the National Masterplan on Wastewater Management. This program was launched for communities with the aim of reaching the $67 \%$ level of canalization for 2010. This program goes as two parallel subprograms as
$>$ Sewage treatment program of Hungary for the smaller settlements and the
> Sewage treatment program of the Capital and the cities with county status,
There are some basic reasons for this differentiation. The financial capabilities of the smaller settlement are lower, so higher rate of State grant seems to be needed in order to start a sanitation program compared with the big towns. The investment capital need of the big cities is so high that even with a lower grant rate, they could dramatically decrease the possibilities of the smaller settlements in case of their joint management.

Separate programs were launched for the protection of existing and future well field areas, as:
> Program on increasing the security of well field areas in use and the
> Program on increasing the security of future well field areas
The reason for differentiation between these programs is that the responsibility for the drinking water resources in use relies on the user of the resource directly, and the State is involved via the sate grants only. In case there is no users of future water resources, the total responsibility relies on the state. These programs basically focuses on the diagnostical issues (i.e. to examine the existing and necessary level of information on the security of these well field areas, identification of pollution sources, the actions to be taken). The actions themselves are intended to be implemented from the sources of the different central funds in a latter step.
Program on municipal waste management was started also, as the big problems were understood on the environment and the human health hazard in the municipal sector, due to the lack of sound waste management. This program touches mostly the groundwater pollution reduction.
Table 3.1.-1: Summary of Recommended Projects for Municipal Hot Spots

| Hot Spot Name, River \& Location | Parameters \& Values which Define the Problem | Ranking of the Problem | Name \& Type of Project | Project Strategy \& Targets | Parameters \& Values which Define Project Benefits | Project Beneficiaries |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Budapest Danube | Population: 1886000 p <br> Sewerage: 90 \% <br> ww: $7000000 \mathrm{~m}^{3} / \mathrm{d}$ | Very high | North Budapest WWTP | Increase the capacity and treatment efficiency | $\begin{aligned} & 200000 \mathrm{~m}^{3} / \mathrm{d} \\ & \text { COD: } 93 \mathrm{mg} / \mathrm{l} \\ & \text { P: } 4 \mathrm{mg} / \mathrm{l} \\ & \hline \end{aligned}$ | Population living downstream on the Danube |
| Budapest, <br> Danube | Population: 1886000 p <br> Sewerage: 90 \% <br> ww: $700000 \mathrm{~m}^{3} / \mathrm{d}$ | Very high | South Pest WWTP | Increase the capacity and treatment efficiency | $\begin{aligned} & 120000 \mathrm{~m}^{3} / \mathrm{d} \\ & \mathrm{~N}, \text { P removal } \end{aligned}$ | Water users downstream, Recreational area at RSD oxbow |

### 3.2.2. Reduction of Water Pollution from Agriculture

## Prevention of Pollution from Agricultural Point Sources

The actions on water pollution reduction from agricultural point sources belong to the same categories with industrial point sources in Hungary. They are handled with usual authority tools. The owner of the pollution source is responsible for the effluent quality. He can give application for State grant form different central funds for the development of pollution reduction facilities. The applicant and the project will likely be judged as it was with an industrial project. There are no defined central agricultural point source pollution projects in Hungary now. The possible reason is likely in connection with the transition nature of agriculture and uncertainties connected with it. The idea of good agricultural practice is known, but it has not been built in into the Hungarian water pollution control policy. Further development is needed in this field, which covers the area of
$>$ construction of storage tanks for liquid manure;
$>$ correct use of manure according to capability of vegetation and cultivated land;
$>$ agro-technical measures like improved live-stock practices;
$>$ collection of effluents from storage of silageamong others.
It seems to be likely that a non-physical project would be useful for the clear definition of an agricultural point source pollution reduction program, and its implementation.

## Prevention of Pollution from Agricultural Non-Point Sources

The level of pollution from agricultural non-point sources has decreased dramatically with the changes of the Hungarian agricultural profile. The fertilizer and pesticide use propped down to $10 \%$ of the maximum level due to the decrease of the State subsidies on their use. The majority of the big animal farms were stopped due to economic reasons.
The relative importance of agricultural non-point source pollution reduction is increasing again today in Hungary, especially in the watersheds of the big shallow lakes, and in catchment areas of small creeks with intensive land uses. Our knowledge is limited on the real level of pollution load due to the weaknesses of the monitoring system and owing to the complexity of the problem itself.

We have not identified yet specific geographical areas (agro-ecological zones) and projects and policy measures that respond to different forms of agricultural non point source pollution. A separate program seems to be necessary to turn the invaluable, excess water endangered agricultural territories into forest in harmony with the ecological corridor and water related ecosystem protection programs of the national nature conservation agencies.
The pesticide use is on so low level that it would not be easy to reduce it further. Measures would be needed to prevent the unnecessary increase of use in future. The use of Lindane, DDT and other persistent pesticides, insecticides is prohibited in Hungary.

There is a central fund with the aim of helping arable land amelioration and erosion control. It works on application basis also. Direct program on erosion control with well-defined technical content does not exist in Hungary.

The idea of strengthening institutional capacities of agricultural pollution reduction exists in Hungary. It worked efficiently in the form of regional institutions for soil protection and pesticide control when the big co-operatives existed. These agencies have limited capacities today and they were not always able to accommodate themselves to the new changes in the ownership structure. The concept on organic farming and low input agriculture is known in Hungary. There are pilot areas for demonstration of the environmental advantages of the idea. The widening of the activity is hindered to an extent due to the shortage of economically feasible examples in Hungary.

Due to the facts mentioned before the expert team of the project came to the conclusion that there are no significant pollution sources with international possible effects in the agricultural sector in Hungary, so we have not proposed agricultural project to be included to the hot spot list.

## Reduction of Water Pollution through Improved Land Management

There are centrally organized programs connected with several sensitive areas where the water contamination exceeds the tolerable level, or it is likely will exceed it without a counteraction. These programs concentrate on general environmental remedial measures, physical development of the region, and water protection has usually a separate, but important role in them. These programs are discussed in 7.1. chapter of Part A so we count them here only.
Protection program on Lake Balaton covers all field of environmental protection on the watershed. The major attention is paid for water pollution reduction. Wetlands are proposed there for diffuse source pollution control especially for runoff control in inner areas of the settlements and from agricultural lands.
Program on the great Hungarian Plain is a general environmental and physical development program. The protection of the oxbows of the Tisza River has specific importance there.
Program on increasing the water management conditions in the Mid-Danube-Tisza Region focuses on the water quantity issues mostly, but its implementation could serve water quality goals also.

## Reduction of the environmental damages at Szigetköz region

One basic aim of this program to protect the water related ecosystems endangered by the BősNagymaros dam system implemented partly and stopped later in connection with increased environmental risk. The program is strongly related with nature close river management.
Program on environmental remediation of contaminated areas belonging to State responsibility.
This program does not deal directly with surface water related issues. Priority is given to those remediation projects where groundwater or sensitive surface water is endangered.

## Program on the rehabilitation of the abandoned old mines

This program focuses on old mine pit areas where the responsible person for their rehabilitation can not be found. The majority of these degraded areas are partly covered with water. The goal of the rehabilitation in most cases is to develop the area into a nature close wetland with considerable nature conservation and tourist value.

## National Environmental Health Action Program

This program is in connection with healthy drinking water supply, and has some connection with the safety of water related ecosystems.

## Program on National Ecological Network

This program will likely be in close connection with surface water protection later. In the firs phase the inventory of the valuable water related biotops were set up. Their condition is far from the required mostly. Some of them are especially endangered from the intensive land uses. Special attention could be afforded towards the wetland areas near to the border territories of the country. These areas were in relative safety due to the political uncertainties in the border regions. This situation has altered with the political changes and the danger of their destroy has increased.
These programs are mostly based on State grants, as the own contribution of the municipalities, or other responsible parties is not higher than $20-50 \%$ generally. There is a co-operation between the mentioned programs, as for instance the application for grant of a community on wastewater treatment development has priority when it can be found on a vulnerable well-field area.

The Hungarian national workshop on target oriented program management organized in the frame of this project came to the conclusion that there are important issues on the field of protection water, and water related ecosystems what can not be counted to one sector only as industry or municipalities. An example was discussed in detail as the rehabilitation of the wetland area at the Danube-Drava confluence and its neighborhood. This so-called "multisectoral" project is in connection with river management, water pollution reduction, natural conservation, agriculture and international co-operation, as the area belongs partly to Hungary and Croatia. There was a conclusion of the workshop, that this project proposal should be included into the group of hot spots with international importance.

### 3.3. Reduction of Water Pollution from Industries

As it was mentioned the pollution reduction of the industrial sector is acceptable compared with other sectors in spite of the fact that about $80 \%$ of the controlled industrial plants exceed the effluent requirement in one parameter as a minimum. State grant is available for the non-compliant factories for further development on application basis. The interest of the industrial plants is not too high for these grants due to the low driving force of the Hungarian water pollution reduction enforcement system. It seems to be likely that a specific program should be launched in connection with the introduction of BATNEEC and BAT into the Hungarian water protection policy. The legal tool of the so-called technological effluent standard system is under development now.

There are no specific targeted national programs on the field of industrial water protection in Hungary today. The responsible regional environmental authority handles industrial water users individually with the existing administrative tools. The authority usually launches a complex environmental check-up in the case of exceeding significantly the effluent standards. The usual result is an action program prepared by the polluter and adopted by the authority. The authority checks not only the effluent quality, but the implementation of the action program also. The polluter can apply for grant or loan from the central funds, and it is not unusual that he gets a grace period on fining to allow him to afford more sources on pollution abatement.
The industrial WWTP-s are sometimes in obsolete condition due to their ages and the economic problems of the factories. It is not unusual that they were not able to follow the changes of the production profile, capacity, etc. Industrial pre-treatment program seems to be important in the case of industries connected to the municipal sewer system, with special regard for the heavy metal content of the WWTP-sludge and its possible use in agriculture.

The statistics on accidental water pollution shows that about $80 \%$ of the events are connected with oil contamination. Special efforts should be taken for prevention of accidental pollution of the Hungarian water bodies. All the industrial plants causing considerable risk of pollution should have their accidental pollution prevention and response plan according to law. These plans were mostly prepared more than 15 years ago, so they hardly reflect the actual conditions. Program seems to be necessary for the development of the industrial accidental pollution prevention plans.
The mentioned target oriented planning workshop emphasized the risk of oil pollution from shipping. The Hungarian historical data on accidental pollution do not support strongly this statement. The Danube international accidental pollution monitoring system (PIAC) has not reported events of this type. We would not propose specific interactions in this field.

The biggest oil refinery in Hungary at Százhalombatta belongs to our list of hotspots. The development of industrial water management system, industrial sewer reconstruction and a new WWTP construction seems to be necessary. This development could decrease the oil pollution load of the Danube considerably.

### 3.4. Reduction of Water Pollution from Dump Sites

### 3.4.1. Municipal Waste Management

Municipal waste collection and management belongs to the responsibility of the local governments in Hungary, as their basic (i.e. obligatory) task. Due to the constant financial shortages they looked for cheap solutions sometimes, and environmental safety was a secondary issue in the past. As a consequence the bigger part of the municipal waste dumps causes risk of pollution for the surface-, or groundwater.

The central funds regard the construction of environmentally safe new waste dumps as high priority. Usually specific advantages are given for applications from the regions where vulnerable groundwater resources can be found, or from the watersheds of sensitive surface waters, and where more than two settlements are involved in the development project. There is no central fund available for settlements where another waste dump was built (or is under construction) in the distance less than 15 km .
It is not unusual that illegal waste dumps can be found around the settlements in abandoned open pit mines and other remote places. The local governments try to control this tendency with limited success. The best counteraction is according to the experiences when the local government collects the waste fee as a lump sum, independently from the amount of waste collected from the site owners, and the amount of collected fee is set up on the level, which cover the legal waste collection and illegal waste dump remediation also.

### 3.4.2. Municipal Liquid Wastes

The municipal liquid wastes have specific importance in Hungary as the quantity is relatively high compared with western countries.

The gap between the level of public water supply and wastewater collection caused high increase of ammonium and nitrate in the wells settled on shallow groundwater in some settlements by the mid of seventies. The local authorities in case of new house construction since that time have prescribed closed wastewater storage tanks in order to tackle with this problem. The cost of wastewater transportation was too high, and the authorities were not able to check strictly these requirements. The inhabitants looked for cheaper - but not fully legal - solutions. Permeable storage tanks were built, where the local conditions made it possible. These solutions were unfeasible where the groundwater table was too high.

The liquid waste collected was transported in normal cases into designated areas, where the environmental risk was felt to be smaller. These dumping sites have not been safe completely, so they are counted as pollution sources to groundwater today.
It is a more serious issue when the liquid waste is dumped into small ditches and creeks illegally by the transporter, what is not totally unusual. The discovered events are handled as legal case, but the level of control is not high enough in this field due to the weaknesses of the local environmental protection. The liquid waste poured into the ditches appears as "diffuse" pollution from agriculture later. The necessary actions to handle these problems are
$>$ increase the level of wastewater collection by municipal sewer systems,
$>$ promotion the environmentally sound individual on site wastewater management facilities,
$>$ Increase the level of control on liquid waste transportation.

Specific program seems to be necessary for increasing the rate of on site wastewater management facilities with special regard for the fact that about $30 \%$ of the population will live on unsewered areas even on a long term basis in Hungary, according to the National Masterplan on Wastewater Management.

### 3.4.3. Hazardous Wastes

The hazardous waste management is strictly regulated in Hungary by law. All industrial wastes should be regarded as hazardous, unless the lack of harm has been proven. The activities that use dangerous substances, or can produce hazardous wastes are obliged to produce mass balances for their technologies. The technical standards of temporary storage inside the factory are regulated. Accredited contractor can do the transportation, with proper technical capabilities and strict administrative discipline. The long-term temporary storage is prohibited.
There are some environmentally safe regional hazardous waste deposition sites and a hazardous waste thermal decomposition plant in Hungary. There are efforts for construction new unites, but the strong opposition of the local population hinders the development.

The environmental authorities pay great attention towards this issue. They control the hazardous waste producers regularly.

Due to the fact that environmentally safe hazardous waste management is very expensive it is not unusual that illegal hazardous waste dumping issues come to light. These are legal cases when the original owner of the waste can be found. In another case the State bears the responsibility for the remediation.
Generally we think that the harm of water pollution from hazardous wastes is on the tolerable level in Hungary.

### 3.4.4. Pollution from Old Dump Sites

There are several examples of pollution from old industrial waste dumpsites from the time when the importance of environmental protection was not recognized. This issue has specific importance, as these pollution sources mostly endanger the groundwater resources, and the overwhelming part of Hungarian drinking water comes from underground water resources.

Specific State program was organized for the survey, localization and liquidation of these dump sites in 1997. This program is planned to be finished in 2005, with the yearly expenditure of $5-35$ million USD. Foreign help was joined to this program from the financial resources of USTDA.

### 3.5. Special Policy Measures

We have described before the development of the Hungarian water legislation as a specific nonphysical project. The new legislation will cover the whole area of water quality protection. The basis is the new environmental bill, the new bill on water management and the draft of the EU framework directive on the protection and sustainable use of water. The introduction of the basic elements of this new legislation can be found in Annexes. The major elements are

1. Designation of watersheds as water quality management units
2. Setting up use related and environmental Water Quality Objectives (WQO), depending on the characteristic land uses and their water quality needs and on basic environmental requirements on the watershed,
3. These WQO-s should be harmonized with EC Directives,
4. Methodology and regulation for clear transition of WQO-s into discharge standards,
5. Launch prioritized, phased, achievable, affordable water quality management programs on watershed level, built up from local community wastewater management plans,
6. Designate the ownership for the objectives and improvement plans to the Catchment Planning Committee,
7. Define clearly the responsibilities and accountabilities of these Catchment Planning Committees,
8. Build up efficient permitting and enforcement instruments,
9. Develop sound monitoring and reporting system on watershed level,
10. Introduce simple, clear, efficient funding and charging systems, base it with a sound revenue as the water discharge fee,
11. Ensure adequate and technically competent staff for water pollution control,
12. Give efficient legal framework for the authority to operate and control the system.

As it can be seen this is a complex legislative work, so priority should be given to the financial issues as water discharge fee and the development of the permitting system, together with the new effluent standards and to the tools of watershed management planning.
Further central programs would be needed to tackle with specific pollution reduction issues as

1. On site wastewater management program in the municipal sector
2. Development of a specific agricultural point source pollution reduction program, and its implementation.
3. Introduction of environmentally good agricultural practices into the agriculture, and to build it into the Hungarian water pollution control policy.
4. Environmental forestation program
5. National erosion control and land management program
6. Industrial pre-treatment program
7. Industrial accidental pollution prevention plans.

## 4. Expected Effects of Current and Planned Projects and Policy Measures

There are several programs under implementation in Hungary as we introduced them in point 7.1. of Part A these programs go parallel, overlap each other to a certain extent. We are perhaps not wrong saying that some of them expresses priorities inside a bigger programme. In this context we can say that the Hungarian Masterplan for municipal wastewater management summarizes all the efforts in the field of municipal wastewater collection and treatment in Hungary for instance. The major part of the Lake Balaton Protection Program refers also to municipal wastewater protection, but with special regard for a specific catchment area, the Balaton watershed. It works so in practice that a settlement lying on the Balaton catchment has an advantage compared with other settlements when applying for grants to the central funds supposing that its goals fit into the National Wastewater Masterplan.

Due to the nature of the National Programs, it is not easy to give estimation of their effect on the water pollution reduction generally and even more problematic to judge its effects separately. The other common character of these national programs is that they do not express their benefits in pollution load reduction values. They refer to statistic data (i.e. the future rate of wastewater collection and treatment, etc.), time horizon of implementation and cost consequences. There are no estimations available regarding the future industrial water pollution. The same is valid for the agricultural water pollution with the difference that there is big uncertainty even on the existing level of water pollution also.
Altogether we are not in the position to give quantitative estimations on the possible reduction of nutrient emissions, hazardous substances pollution load, microbiological contamination of the ongoing and suggested central programs.

We have made our expert judgement on the pollution reduction coming from the implementation of the Municipal Wastewater Masterplan, supposing that all the effort related to the municipal wastewater management are summarized in this program. We would remain on the opinion that the pollution from industrial and agricultural pollution sources will remain in the existing level as general consequence of the different tendencies.

### 4.1. Reduction of Organic Materials

The total pollution load coming from the municipal sector (inhabitants and institutions together) can be estimated as 18 million personal equivalents (PE). Today its $44 \%$ are connected to sewer, but only half of the collected wastewater is estimated to be treated with proper efficiency. Consequently today about 14 million PE ( $316000 \mathrm{t} \mathrm{BOD} / \mathrm{a}$ ) pollutes the environment (partly the soil, groundwater and surface waters).
After the goals of the Masterplan will have been reached:
The level of total PE produced remains the same, the wastewater collection rate is $67 \%$, the other part is treated by environmentally safe individual systems. The total pollution load to the environment (supposing $90 \%$ overall treatment efficiency) is 1,8 million PE (31 $500 \mathrm{t} \mathrm{BOD} / \mathrm{a}$ ).

### 4.2. Reduction of Nutrient Emissions

We used the same basic estimations for the wastewater collection and treatment as it was mentioned in point 4.1. We supposed that half of the total collected wastewater will be subject of nutrient removal. The overall removal efficiency will be $80 \%$ for phosphorus, and $72 \%$ for total nitrogen. As a result of the calculation we summarize our estimation in the following table:

|  | Total produced t/a | Existing load t/a | Future load t/a | Reduction |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Quantity t/a | Rate \% |
| Phosphorus | 23000 | 21700 | 9200 | 12500 | 58 |
| Total <br> Nitrogen | 79000 | 70200 | 29500 | 40700 | 58 |

The rate between the water and soil pollution will depend on the individual decisions on the possible recipients in the future development projects.

### 4.3. Hazardous Substances

The available data on hazardous substances emissions are not enough for doing estimation on the existing level of pollution, and the possible reduction owing to the different control measurements.

### 4.4. Adverse Effects of Pollution Reduction

It is clear that the environmental balance of the planned water pollution reduction actions is positive to an overwhelming extent. One important adverse environmental effect can be mentioned. Namely the pollution load from the municipal sector to surface waters will increase to a certain extent due to the increased level of wastewater collection, even after efficient treatment processes. This issue is important in case of sensitive standing waters only. Consequently there is a required maximum level of wastewater collection in sensitive watersheds to be calculated on the basis of careful evaluation. This issue was examined on the Balaton watershed in Hungary. The conclusion was that

The soil should be regarded as recipient in case of small settlements, where there is no risk for pollution of groundwater resources.
The other adverse effect, which should be considered, is that a big part of the population on some watersheds is not able to bear the economic consequences of the increased level of water services. Surveys connected to World Bank projects gave the results that the costs of water services can reach the $5-7$ \% level of the income of the lowest income quartile population in big towns. We suppose that this rate can be the double of the mentioned in the case of small villages. We think, this level is hardly tolerable for the consumers. Specific efforts, low cost technical solutions, step by step development projects with minimum advance investments and economical service companies are needed to manage this problem.

### 4.5. Transboundary Effects

Hungary has two rivers where considerable pollution load leaves the country. The pollution loads of the upstream and downstream border sections are nearly the same on Danube due to its big selfpurification capacity. We await that considerable decrease will occur after the discussed pollution reduction programs will be finished.

Important water related ecosystem, worth for interest even on European level could be saved at the Hungarian-Serbian border region in case of implementation of the Danube Drava rehabilitation project proposed on the project list.

There is a significant difference in the upstream and downstream water quality of the Tisza River due to the pollution load from Slovakia Republic, Romania and to the pollution with home origin. Significant improvement is awaited due to the project implementation at Szolnok and Szeged. Further improvements are needed in other riparian countries for reaching a tolerable water quality at the southern section of Tisza.

## 5. Cost Estimation of Programs and Projects

Recently the state continues to be the major investor in the area of wastewater treatment investments

Hungary's first priority among the water sector programmes (see Table 5.1.) is the Wastewater Treatment Programme. There has been elaborated a special decision of the Government about the support of mentioned programme. The Governmental support is manifested in form of subsidizing projects from ministerial budget and stimulating and supporting wide involvement of international financial institutions

The basis of our proposal on hotspots is the analysis of the water quality in Hungary, and the changes when the rivers enter and leave the country. The effects of pollution loads on ecosystem and human health are basically influenced by the self-purification capacity of the big rivers leaving the country. This is the reason why we can not speak about big changes in water quality of the big transboundary rivers in Hungary. The list of our hotspot proposal can be seen in Table 5.2.

The results of this ranking reflect the general situation in Hungary as the major tasks on water pollution reduction can be found in the municipal sector. We propose that 6 projects should belong to this category.
The biggest oil and chemical industrial plants belong to the industrial hotspots. They have their wastewater treatment facilities, but they have to be developed, or reconstructed mostly together with their industrial sewer systems. There is one industrial hotspot - the BORSODCHEM Company - where a special problem needs to be solved owing to the high salt pollution of the recipient.

We proposed 1 high priority hotspot with "inter-sectoral" nature. This proposal focuses on the rehabilitation of the water-related ecosystems in the Hungarian- Croatian transboundary region.

All these high priority hotspots are introduced in the Project Files attached to the summary report. We can conclude that the key issue of investment into water pollution reduction at the high priority hotspot is the bankability of the projects.
The cost estimation of the high priority hotspots is summarized in table 10 . We can conclude that

| Total for Project Portfolio: | Million HUF | $33,018.00$ |
| :--- | ---: | ---: |
|  | Million USD | 160.94 |
| Non-secured: | Million HUF | $19,345.00$ |
|  | Million USD | 94.30 |
| Secured: | Million HUF | $13,673.00$ |

## 6. Planning and Implementing Capacities

As we discussed before the law enforcement should be increased in Hungary as a basic element of the institutional capacity. New regulation is needed in the field of water quality planning, effluent standards related to the in stream water quality and to the technology used. The effluent monitoring capacity should be strengthened also via widening role of the self-monitoring and quality assurance.

Wastewater treatment should be obligatory for all municipal polluters also. Personal responsibility should be given for the water pollution caused. River basin organizations should be set up as holders of responsibility for the good quality of water. The awareness of public should be increased towards water quality issues.

The introduction of the wastewater discharge fee would be a major step on water quality protection, as it would increase the interest of polluters in pollution reduction.

The design capacity is basically available on the field of civil engineering in Hungary. The big State owned design institutes have gone into small private design enterprises. These companies are very active in the field of wastewater treatment plant and sewerage design. Design quality assurance should be increased. These planing bureaus are in good connection with the local governments, which are the most important stakeholders of the water pollution reduction. They have got experiences for co-operation with the foreign consulting companies, investors and donors. These small companies usually can not connect enough financial guaranty to their contracts.

There is a boom in the civil engineering construction sector in Hungary today, due to the considerable amount of State support in the field of municipal sewerage and wastewater treatment development. This situation has given the possibility for development of strong construction companies who are basically capable to solve all the emerging tasks. These companies are owned by foreign capital due to the privatization procedure going on in Hungary. The regulation for public procurement is in rule. The raw materials and machinery needed in the water protection business are available from home production and from imports. The choice of the contractor depends on the decision of the investor. It is not unusual that foreign goods are the winners of competition when value and price are evaluated together.
There are examples of international co-operation in running water service companies on concession basis. The experiences are limited of this type of co-operation due to the relatively short time spent in this field. It is a common experience that it is not too easy to find room for a long-term contract with fixed financial terms in the transition period of the water sector.

Annexes

## The Trends of Development in the Hungarian Water Legislation

The hypothesis of the proposed new water legislation is that the basis for water quality management and regulation is the river basin. The river basin is the smallest natural unit of water protection where the needs of land uses can be taken into account, the possible conflicts of the water users and polluters, or that of the upstream and downstream water users can be understood clearly by all interested parties. The clear situation can assist reasonable and economic solutions for reducing water pollution and enable the interest of the parties for setting up the goals regarding water quality to be achieved on gradual, tolerable way, avoiding unaffordable economic burden to local inhabitants. The new legislation targeted the application of the worldwide experiences of integrated river basin management to Hungarian circumstances.
It is clear also that through the elements of the new water legislation should be based on the foreign experiences, caution is suggested towards brand new, untested legal solutions. The specific, Hungarian law enforcement experiences should be taken into consideration too.
An important component of the legislative work was the investigation of the potential environmental, economic and social impacts of different regulatory approaches in selected case study areas. Water management computer models calculated these impacts. Five significantly differing test sites were selected as case study areas, in order to give sound basis for nation-wide extrapolation of the results with the help of a PHARE project (DHV Hungary, 1996).

The basic aims are to secure the institutional background for avoiding the deterioration of the receiving water qualities, determination of the desired water quality improvements, incorporation of the EC Directives, the development of a sustainable water quality protection strategy, specification of the required effluent quality through a system of individual, time related discharge permits, effective enforcement to ensure permit compliance. Additionally a proposal was needed for a more efficient system of revenue collection for water pollution investments and for financing partly the water protection control activities.
The present National water quality management system has been found too inflexible to deal with such spread issues, thus leading to a need of local involvement into surface and groundwater protection. It is vital that local activities should fit into the National framework, in order to maintain the general consistency, and allow harmonization with EC Directives generally.

The basic elements of the water quality management system can be summarized as
> use related Water Quality Objectives (WQO), depending on the characteristic land uses and their water quality needs on the watershed;
> WQO-s should be harmonized with EC Directives;
$>$ clear transition of WQO-s into discharge standards;
> prioritized, phased, achievable, affordable water quality management programs on watershed level, built up from local community wastewater management plans;
> ownership for the objectives and improvement plans;
> clear responsibilities and accountabilities;
> efficient permitting and enforcement;
> sound monitoring and reporting system;
$>$ simple, clear, efficient funding and charging systems;
$>$ adequate and technically competent staff for water pollution control;
> legal framework to be given for the authority to provide and operate the system.

## Water quality objectives

The first EC Action Program for the Environment stressed the need of establishing quality objectives on Community level in 1973. The draft Water Resources Framework Directive proposes that a system of use related WQO-s should be developed covering all identified river catchments and aquifers. The water uses for which quality criteria has been developed are
$>$ drinking water;
$>$ bathing/recreational waters;
$>$ irrigation;
$>$ fisheries and ecological protection;
$>$ general amenity.
Whilst use-related objectives are here advocated as the principal management approach it should be noted that in several cases these objectives on their own will not be sufficient to tackle serious pollution problems. In these cases an emission limit value approach is recommended connected with the Best Available Technology (BAT) especially in case of toxic substances.

## Catchment based planning

The Watershed Water Quality Management Plan gives the basis for the approach outlined before. It is essential that catchment based approach is adopted in order to set up WQO-s on a comprehensive manner, taking into consideration the influence of upstream pollution for downstream water quality. This approach enables us to prioritize and phasing the investments and other actions throughout the catchment area. The catchment approach allows the incorporation of the effects to diffuse pollution sources, and the integrated evaluation of water quantity and quality issues in the management plan.
The catchment management plan gives the basis for
$>$ local municipal sewerage plans and wastewater treatment for the settlements including the designation of sewerage and individual onsite zones;
$>$ local water quality plans for industrial and commercial polluters with the definition of water needs, effluent characteristics, accidental pollution prevention requirements;
$>$ local water quality plans for agriculture including measures covering priority farms and feedlots with focus on land use requirements, amelioration programmes, runoff control, use od chemicals, feedlot technology, manure disposal and utilization.

## Monitoring and evaluation

The transition towards catchment based planning and integrated water quality management requires information available on catchment basis, and covers all relevant aspects. The project gave the following recommendations in this respect:
$>$ reorganization of the existing surface and groundwater monitoring networks on catchment basis in order to support catchment planning;
$>$ upgrading emission monitoring considerably so it may facilitate water quality management. General experience is that the existing emission monitoring system is the weakest point of the water quality planning;
$>$ the improved effluent monitoring policy should contain higher rate of monitored discharges, higher monitoring frequency, proportional monitoring for larger polluters, extension of the self monitoring practice with authority control;
$>$ data collection and systematic data change with all relevant institutions on the watershed such as land uses, water uses, meteorological data, public health information etc.;
$>$ organization of one database containing all relevant information, by allocating the tasks and responsibilities regarding data availability and transfer;
$>$ development of harmonized data quality assurance;
$>$ regular overview of the catchment monitoring system.
The major part of the data needed on national level may be imported from the proposed catchment monitoring systems. This catchment monitoring can fulfil to much extent the data requirements of the local wastewater management plans also, but additional targeted surveys seem to be necessary in this case.

The Environmental Bill decides on the freedom of access to the environmental data. Lower level of regulation is awaited on the daily data use that can clarify the procedures.
Different water quality evaluation methods were proposed ranging from the development of the existing National Standards, development of a system for evaluation based on use related water quality requirements, toxicity index and function specific indexes for recipients with specific ecological function. Development of standardized evaluation methods for all methods was proposed.

## Wastewater collection standards

At present there are no direct obligations for wastewater collection for the municipalities in Hungary. The local government is responsible for public wastewater management "depending on its abilities", according to the regulations. In spite of this confusing regulation big local interest can be experienced for wastewater infrastructure development due to the advantageous State subsidy mechanism, which can not force the efficient technical solutions to appropriate extent.
The EC Urban Wastewater Directive requires the sewerage of the settlements with higher then 2000 population-equivalent, but does not give guidance on the necessary level of wastewater collection rate.
The optimum level of wastewater collection should be decided in the local wastewater management plan.

## Emission standards

The adoption of the water quality objective approach leads directly to the establishment of appropriate emission standards to be referred for the quality, which is necessary to achieve in the receiving watercourse. We can calculate the permissible input from a discharge at a given point of the recipient by using standardized calculation techniques. The permissible load can be accepted by the watercourse taking into consideration the dilution and natural purification.
The EC Urban Wastewater Directive prescribes the minimum treatment requirements depending on the size of the settlements, setting up specific additional standards in case of recipient sensitive for eutrophication. The Hungarian water protection policy has adopted the concept of effluent standard based on technological considerations the reasonable and accessible production-, or abatement techniques.
It is usual that especially in case of recipient with high dilution capacity, the effluent limit based on the permissible load concept seems to be too lose compared to the basic treatment requirements settled down in the EC Urban Wastewater Directive, or in relating other technological effluent standards. The stricter requirement was suggested to follow, according to the combined approach in this case.

## Non point source pollution assessment.

Diffuse pollution can hardly be directly monitored. It is usually estimated by deduction of point source load from total pollution calculated in the receiving water body. More reliable data could be awaited after having improved the point source monitoring system. Additional research work is needed also for the better estimation of diffuse pollution from agricultural sources and from urban runoff.

A part of the diffuse pollution load is a consequence of illegal activities as illegal septage disposal into small ditches and creeks, and uncontrolled sludge bypass to the recipient from wastewater treatment plants. More efficient authority control and more effective disincentive system can decrease the effect of this activity.

The stormwater overflow should also be monitored in case of sensitive recipient.

## Institutional development

Having outlined the principles of the technical approach to be adopted it is necessary to examine the institutional machinery, which is capable to define the catchment management plans. The crucial element of the process outlined before is the full local involvement so that the objectives and plans should be "owned" by the communities, industries, water users etc. affected by any resulting proposals. It is clear that the objectives might be achieved when there are established new bodies as so called Catchment Planning Commissions for each catchment area.

These Commissions would be established by the responsible Ministry, and accountable also for the Ministry. They would be responsible for setting up locally agreed WQO-s, for development management plans, preparation of annual reports on the progress of the local wastewater management plans. The Commission could work as a board drawn from representatives of all parties interested in water quality management. The responsibility of the Commission covers water quantity and quality issues in order to provide an integrated approach to water resources management according to the EC Water Resources Framework Directive.

The catchment areas could be defined in a pragmatic way, taking into consideration land uses, administrative borders. Basically they could be small to give the possibility for clear understanding of the different interests for all interested parties, and the limitations of the administrative cost is also important on the other hand.

It was experienced that the level of responsibility to be delegated to the Commission is a sensitive issue for the existing administrative bodies, so the legal proposals limited themselves for the proposition of a partial river basin approach. It seemed to be unrealistic to follow strictly the full institutional consequences of the river basin approach immediately, but on a step by step approach in future.

## Charging principles

The Environmental Charge would provide an assured revenue stream on a consistent basis. This charge would be levied on all discharges according to the pollutant input allowed in their permits (giving possibility for them to apply for the decrease of their effluent standards when they want it). There are different options regarding the target to be reached by the charging system as
$>$ to cover the administrative costs of water quality management including the costs of the activity of regional water authorities, the Catchment Management Commissions;
$>$ to raise revenues for funding water protection investment programmes. The overall level of charge in this option is the result of balancing between needs and social consequences;
> to provide incentive for the polluters to reduce pollution beyond the level allowed in the permit. The level of charge needs to be comparable with the incremental pollution reduction costs.

In the light of the consultations with the decision-makers, the system based on the combination of the first two options was proposed, taking into consideration that public affordability is a serious political issue today in Hungary.

## State subsidies

It is clear form the experiences of other countries that water quality protection could not be managed without substantial contribution of the State. The State fund is needed for speeding up the pollution reduction programme, for equalization of differences in affordability from local resources.
It may be envisaged that the State funding philosophy should be based on the National Action Programme for Wastewater management, which is part of the National Environmental Programme. The subsidy mechanism should have a clear, auditable decision procedure with close monetary control.

## Legal framework

In order to implement the proposals summarized above efficiently it is essential that clear legal framework exists and provides the authority to establish and operate the Water Quality Management System. There is a number of key issues to be addressed.
> The status of Water Quality Objectives should have the power of law as the foundation on which all improvement plans are based.
> The establishment of Catchment Planning Commission, their duties and responsibilities, financial sources of their activity.
> Determination of the transitional period and procedure for the introduction of the phased approach.
> The environmental charge should be recognized in law.
$>$ Several other issues should be regulated as the connection between the Catchment Commission and the regional authorities, legal obligation for sewerage connection on sewered areas.

## Enforcement and criminalization

The present Hungarian area category system fails to truly honor water quality objectives. It is therefore less suitable basis for the effective formulation of objectives, which is a prerequisite for formulating cost-effective sanitation.
The case studies also indicated that water quality objectives could hardly be achieved by sanitation plans only. In most areas non-point source pollution has an overwhelming influence on water quality and needs to be addressed. Cost-effective sanitation requires an integrated approach, which comprises the formulation of water quality objectives and the necessary water quality measures within river basin plans.
River basin planning may in theory and practice be best implemented by river basin authorities with far reaching tasks and responsibilities in the management of ground and surface waters.
However, since this would involve also far reaching reorganization, a procedural solution that enables the formulation of integrated plans, but allows their implementation and supervision by existing authorities and companies, i.e., the partial river basin approach was favored.
Based on the research in case of study areas, legal implications were determined. A transition towards a river basin approach was proposed and comprised various recommendations and elements. The most important of these recommendations is the installment of a planning body, the Catchment Planning Commission, that is served by the respective environmental inspectorate and has the responsibility to make water quality management for river catchment.

In order to facilitate and enable the formulation of cost-effective sanitation plans, a standard system was proposed that is based on the use-related water quality objectives. These objectives are related to minimum sanitation requirements that are harmonized with EU-directives.

It was also proposed to upgrade the existing fining system, adjusting it to today's prices and the newly proposed standard system, and to use it only as an incentive but not for revenue raising. Revenue raising should be done on the basis of environmental fees that will essentially cover the annual costs of capital depreciation, operation and maintenance. The water and sewage fee system should be simple to use in the short term built-in possibilities to differentiate it in future, so it may generate catchment specific incentives to pollution abatement as well.
